Example: TM for binary successor

$p \in K$	$\sigma \in \Sigma$	$\delta(p, \sigma)$
s	0	$(s, 0, \rightarrow)$
s	1	$(s, 1, \rightarrow)$
s	\sqcup	(q, \sqcup, \leftarrow)
s	\triangleright	$(s, \triangleright, \rightarrow)$
q	0	$(h, 1, -)$
q	1	$(q, 0, \leftarrow)$
q	\triangleright	$(h, \triangleright, \rightarrow)$

➔ **Question** : What is the output of this TM on the input 11011?

➔ **Anwer** : 11100

➔ **Question** : What happens on input 1111?

Turing Machines

A (1-string) **Turing machine (TM)** M is a quadruple (K, Σ, δ, s)

- 1 K finite set of states
- 2 Σ finite alphabet (disjoint from K) contains always \sqcup, \triangleright
- 3 δ is the transition function

$$\delta: K \times \Sigma \rightarrow (K \cup \{h, \text{yes}, \text{no}\}) \times \Sigma \times \{\leftarrow, \rightarrow, -\}$$
- 4 s is the initial state

Restriction: If $\delta(p, \triangleright) = (p, \rho, D)$, then $\rho = \triangleright$ and $D = \rightarrow$

Input x of M is written next to \triangleright .

- ➔ if M reaches h , it is **halting**
- ➔ the output y is the string of M at halting $M(x) = y$
- ➔ if it reaches **yes**, it **accepts** $M(x) = \text{yes}$
- ➔ if it reaches **no** it **rejects** $M(x) = \text{no}$

Turing Machine for palindromes

$p \in K$	$\sigma \in \Sigma$	$\delta(p, \sigma)$	$p \in K$	$\sigma \in \Sigma$	$\delta(p, \sigma)$
s	0	$(q_0, \triangleright, \rightarrow)$	q'_0	0	(q, \sqcup, \leftarrow)
s	1	$(q_1, \triangleright, \rightarrow)$	q'_0	1	$(\text{no}, 1, -)$
s	\triangleright	$(s, \triangleright, \rightarrow)$	q'_0	\triangleright	$(\text{yes}, \triangleright, \rightarrow)$
s	\sqcup	$(\text{yes}, \sqcup, -)$	q'_1	0	$(\text{no}, 1, -)$
q_0	0	$(q_0, 0, \rightarrow)$	q'_1	1	(q, \sqcup, \leftarrow)
q_0	1	$(q_0, 1, \rightarrow)$	q'_1	\triangleright	$(\text{yes}, \triangleright, \rightarrow)$
q_0	\sqcup	$(q'_0, \sqcup, \leftarrow)$	q	0	$(q, 0, \leftarrow)$
q_1	0	$(q_1, 0, \rightarrow)$	q	1	$(q, 1, \leftarrow)$
q_1	1	$(q_1, 1, \rightarrow)$	q	\triangleright	$(s, \triangleright, \rightarrow)$
q_1	\sqcup	$(q'_1, \sqcup, \leftarrow)$			

Configuration

→ a **configuration** of M is (q, w, u)

- 1 q is the state
- 2 w is the string to the left of the cursor, including the symbol scanned by the cursor
- 3 u is the string to the right

consider M on 0010:

$(s, \triangleright, 0010) \quad (q_0, \triangleright \triangleright 010 \sqcup, \epsilon) \quad (q'_0, \triangleright \triangleright 010, \sqcup) \quad (q, \triangleright \triangleright 01, \sqcup \sqcup)$

→ $(q, w, u) \xrightarrow{M} (q', w', u')$ one step from (q, w, u) to (q', w', u')
yields in one step

→ $(q, w, u) \xrightarrow{M^k} (q', w', u')$ k steps yield (q', w', u') from (q, w, u)
yields in k steps

→ $(q, w, u) \xrightarrow{M^*} (q', w', u')$ exists k , $(q, w, u) \xrightarrow{M^k} (q', w', u')$
yields

Many-string Turing Machine

Representation

To solve a problem by a TM, we have to fix a representation of an instance of the problem as string.

- All reasonable representations are polynomially related
Unary coding is **not** reasonable
- **Convention**: Numbers will always be represented in binary.

Definition

A **k -string Turing machine** M is a quadruple (K, Σ, δ, s) .

- 1 K, Σ as before.
- 2 δ is a function

$$\delta: K \times \Sigma^k \rightarrow (K \cup \{h, \text{yes}, \text{no}\}) \times (\Sigma \times \{\leftarrow, \rightarrow, -\})^k$$

- 3 If M computes a function, the output is written on the **last** string.

Turing Machines as Algorithms

$L \subseteq (\Sigma - \{\triangleright, \sqcup\})^*$ be a **language**, M a TM with

- 1 \forall strings $x \in (\Sigma - \{\triangleright, \sqcup\})^*$: if $x \in L$, then $M(x) = \text{yes}$, and if $x \notin L$, then $M(x) = \text{no}$
- 2 M **decides** L ; L is called **recursive** (or **decidable**)

M be a TM with

- 1 \forall strings $x \in (\Sigma - \{\triangleright, \sqcup\})^*$: if $x \in L$, then $M(x) = \text{yes}$, and if $x \notin L$, then M does not terminate
- 2 M **accepts** L ; L is called **recursive enumerable** (or **semi-decidable**)

Fact If L is recursive, then it is recursive enumerable

$f: (\Sigma - \{\triangleright, \sqcup\})^* \rightarrow \Sigma^*$, M be a TM (over Σ), with

- 1 \forall strings $x \in (\Sigma - \{\triangleright, \sqcup\})^*$: $M(x) = f(x)$
- 2 M **computes** f ; f is called **recursive**

Example: TM for palindromes (faster version)

$p \in K$	$\sigma_1 \in \Sigma$	$\sigma_2 \in \Sigma$	$\delta(p, \sigma_1, \sigma_2)$
s	0	\sqcup	$(s, 0, \rightarrow, 0, \rightarrow)$
s	1	\sqcup	$(s, 1, \rightarrow, 1, \rightarrow)$
s	\triangleright	\triangleright	$(s, \triangleright, \rightarrow, \triangleright, \rightarrow)$
s	\sqcup	\sqcup	$(q, \sqcup, \leftarrow, \sqcup, -)$
q	0	\sqcup	$(q, 0, \leftarrow, \sqcup, -)$
q	1	\sqcup	$(q, 1, \leftarrow, \sqcup, -)$
q	\triangleright	\sqcup	$(p, \triangleright, \rightarrow, \sqcup, \leftarrow)$
p	0	0	$(p, 1, \rightarrow, \sqcup, \leftarrow)$
p	1	1	$(p, 1, \rightarrow, \sqcup, \leftarrow)$
p	0	1	$(\text{no}, 1, -, \sqcup, -)$
p	1	0	$(\text{no}, 1, -, \sqcup, -)$
p	\sqcup	\triangleright	$(\text{yes}, \sqcup, -, \triangleright, \rightarrow)$

Configuration (cont'd)

→ A **configuration** of a k -string TMs

$$(q, w_1, u_1, \dots, w_k, u_k)$$

- 1 q is the state
- 2 $w_i u_i$ is the i^{th} string
- 3 the cursor points to the last symbol in w_i

→ $(q, w_1, u_1, \dots, w_k, u_k) \xrightarrow{M} (q', w'_1, u'_1, \dots, w'_k, u'_k)$ one step from $(q, w_1, u_1, \dots, w_k, u_k)$ to $(q', w'_1, u'_1, \dots, w'_k, u'_k)$

→ $(q, w_1, u_1, \dots, w_k, u_k) \xrightarrow{M'} (q', w'_1, u'_1, \dots, w'_k, u'_k)$ / steps

→ $(q, w_1, u_1, \dots, w_k, u_k) \xrightarrow{M^*} (q', w'_1, u'_1, \dots, w'_k, u'_k)$ yields

Consider the 2-string TM M for palindromes:

$$(s, \triangleright, 0010, \triangleright, \epsilon) \xrightarrow{M} (s, \triangleright 0, 010, \triangleright \sqcup, \epsilon) \xrightarrow{M^*} (q, \triangleright 0010, \sqcup, \triangleright 0010, \sqcup)$$

Example: Palindromes

The 1-string Turing machines M for palindromes operates in $\lceil \frac{n}{2} \rceil$ stages and

- first stage: $2n + 1$ steps to compare 1st and last symbol
- second stage: $2(n - 2) + 1$ steps to compare 1st and last symbol
- ...

In total

$$(2n + 1) + (2n - 3) + \dots = \frac{(n + 1)(n + 2)}{2} = f(n)$$

Fact

- 1 The language L of all palindromes is in **TIME**($f(n)$) = **TIME**($\mathcal{O}(n^2)$)
- 2 And with the 2-string Turing machine in **TIME**($\mathcal{O}(n)$)

Time Complexity

→ If for a k -string Turing machine M and input x we have

$$(s, \triangleright, x, \triangleright, \epsilon, \dots, \triangleright, \epsilon) \xrightarrow{M^t} (H, w_1, u_1, \dots, w_k, u_k)$$

then the **time required by M** is t ($H \in \{h, \text{yes}, \text{no}\}$)

→ M operates within time $f(n)$ if, for any input string x , the time required is at most $f(|x|)$

→ $L \in \mathbf{TIME}(f(n))$

if L is decided by a multi-string M operating in time $f(n)$

Theorem

Given any k -string Turing machine M operating within time $f(n)$, we can construct a Turing machine M' operating within time $\mathcal{O}(f(n)^2)$ and $M(x) = M'(x)$.

Proof

Define $M' = (K', \Sigma', \delta', s)$ $\Sigma' = \Sigma \cup \underline{\Sigma} \cup \{\triangleright', \triangleleft, \triangleleft'\}$

Configuration

$$(q, w_1, u_1, \dots, w_k, u_k)$$

in M , becomes

$$(q, \triangleright, w'_1 u_1 \triangleleft w'_2 u_2 \triangleleft \dots w'_k u_k \triangleleft \triangleleft)$$

w'_i equals w_i with \triangleright replaced by \triangleright' and last symbol σ_i by $\underline{\sigma}_i$.

Initial phase.

- 1 Shift input to the right, precede with \triangleright'
- 2 Write $\triangleleft(\triangleright'\triangleleft)^{k-1}\triangleleft$ after the input

Simulation a move in M

- 1 M' scans its string and “remembers” the k currently scanned symbols in M ; remembering is done, by **introducing new states** that represent the states of M and the scanned symbols
- 2 M' scans its string again and simulates one step of M
- 3 If one of the strings is extended in M , M' has to **move** everything after it **to the right**
 - ➔ Replace currently scanned \triangleleft by \triangleleft'
 - ➔ go to the right side (marked by $\triangleleft\triangleleft$)
 - ➔ move everything to the right
 - ➔ when we reach \triangleleft' , replace by $\sqcup\triangleleft$

Fact

total length of the string of M' is never more than $k(f(|x|) + 1) + 1$

Simulating a move at most costs

$$(4k(f(|x|) + 1) + 4 \text{ steps}) + (3k(f(|x|) + 1) + 3 \text{ steps}) \cdot k$$

In total, the (worst-case) time-complexity is

$$\mathcal{O}(k^2 f(|x|)^2) = \mathcal{O}(f(|x|)^2)$$

□
