week 9

# Overview

- Week 9 - Combinator Parsing
  - Summary of Week 8
  - Motivation
  - Combinator Parsing
  - Parsing Simple Arithmetic Expressions

# Overview

- Week 9 - Combinator Parsing
  - Summary of Week 8
    - Motivation
    - Combinator Parsing
    - Parsing Simple Arithmetic Expressions

# Efficiency of Functional Programs

Avoid unnecessary recomputations by ...

- tupling

Introduce tail recursion by ...

- parameter accumulation

# This Week

## Practice I

OCaml introduction, lists, strings, trees

## Theory I

lambda-calculus, evaluation strategies, induction, reasoning about functional programs

## Practice II

efficiency, tail-recursion, **combinator-parsing**

## Theory II

type checking, type inference

## Advanced Topics

lazy evaluation, infinite data structures, monads, ...

# Overview

- Week 9 - Combinator Parsing
  - Summary of Week 8
  - **Motivation**
  - Combinator Parsing
  - Parsing Simple Arithmetic Expressions

# What is Parsing?

*Parsing is the decomposition of a linear sequence into a structure, given by a grammar.*

# What is Parsing?

# What is Parsing?

*Parsing is the decomposition of a linear sequence into a structure, given by a grammar. This linear sequence may be a text in some natural language, a computer program, a web site, a piece of music, a sequence of genes*

# What is Parsing?

*Parsing is the decomposition of a linear sequence into a structure, given by a grammar. This linear sequence may be a text in some natural language, a computer program, a web site, a piece of music, a sequence of genes, ...*

# What is Parsing?

*Parsing is the decomposition of a **linear sequence** into a structure, given by a grammar. This linear sequence may be a text in some natural language, a computer program, a web site, a piece of music, a sequence of genes, ...*

- linear sequence: 't list (list of tokens)

# What is Parsing?

*Parsing is the decomposition of a linear sequence into a **structure**, given by a grammar. This linear sequence may be a text in some natural language, a computer program, a web site, a piece of music, a sequence of genes, ...*

- linear sequence: 't list (list of tokens)
- structure: some user-defined type (abstract syntax tree)

# What is Parsing?

*Parsing is the decomposition of a linear sequence into a structure, given by a **grammar**. This linear sequence may be a text in some natural language, a computer program, a web site, a piece of music, a sequence of genes, ...*

- linear sequence: 't list (list of tokens)
- structure: some user-defined type (abstract syntax tree)
- grammar: BNF (Backus-Naur form)

# What is Parsing?

*Parsing is the decomposition of a linear sequence into a structure, given by a grammar. This linear sequence may be a text in some natural language, a computer program, a web site, a piece of music, a sequence of genes, ...*

- linear sequence: 't list (list of tokens)
- structure: some user-defined type (abstract syntax tree)
- grammar: BNF (Backus-Naur form)

## Note

- BNF can express context-free grammars (CFG)
- combinator parsers can parse context-sensitive grammars
- however, for the purpose of this lecture CFG suffice

# Usual Two Phases - Lexing and Parsing

## Lexing

- divide original input (list of **chars**) into tokens
- white space and comments may be dropped at this stage
- syntactic check

# Usual Two Phases - Lexing and Parsing

## Lexing

- divide original input (list of **chars**) into tokens
- white space and comments may be dropped at this stage
- syntactic check

## Parsing

- work on list of tokens
- check if list of tokens corresponds to grammar
- produce an abstract syntax tree (AST)
- semantic check

# Usual Two Phases - Lexing and Parsing

## Lexing

- divide original input (list of **chars**) into tokens
- white space and comments may be dropped at this stage
- syntactic check

## Parsing

- work on list of tokens
- check if list of tokens corresponds to grammar
- produce an abstract syntax tree (AST)
- semantic check

# Propositional Formulas

## Grammar

$$\phi ::= p \mid (! \phi) \mid (\phi \& \phi)$$

# Propositional Formulas

## Grammar

$$\phi ::= p \mid (! \phi) \mid (\phi \& \phi)$$

## Lexing

token	corresponds to
LPAR	(
RPAR	)
NOT	!
AND	&
ID of string	propositional atom

# Propositional Formulas

## Grammar

$$\phi ::= p \mid (! \phi) \mid (\phi \& \phi)$$

## Lexing

token	corresponds to
LPAR	(
RPAR	)
NOT	!
AND	&
ID of string	propositional atom

## Example

"(a &(!b))"  $\xrightarrow{\text{lexing}}$  [LPAR; ID "a"; AND; LPAR; NOT; ID "b"; RPAR; RPAR]  
 "(a a)"  $\xrightarrow{\text{lexing}}$  [LPAR; ID "a"; ID "a"; RPAR]

# Propositional Formulas (cont'd)

## Grammar

$$\phi ::= p \mid (! \phi) \mid (\phi \& \phi)$$

# Propositional Formulas (cont'd)

## Grammar

$$\phi ::= p \mid (! \phi) \mid (\phi \& \phi)$$

## Parsing (AST)

```
type t = Atom of string
       | And of t * t
       | Not of t
```

# Propositional Formulas (cont'd)

## Grammar

$$\phi ::= p \mid (! \phi) \mid (\phi \& \phi)$$

## Parsing (AST)

```

type t = Atom of string
        | And of t * t
        | Not of t
  
```

## Example

$[LPAR; ID "a"; AND; LPAR; NOT; ID "b"; RPAR; RPAR] \xrightarrow{\text{parsing}}$   
 $And(Atom "a", Not(Atom "b"))$   
 $[LPAR; ID "a"; ID "a"; RPAR] \xrightarrow{\text{parsing}} \times$

# Parsers

## First Attempt

- functions of type `'t list -> ('a * 't list)`
- e.g., `digit ['1';'2']` results in `('1', ['2'])`
- but what about errors

# Parsers

## First Attempt

- functions of type `'t list -> ('a * 't list)`
- e.g., `digit ['1';'2']` results in `('1', ['2'])`
- but what about **errors**

# Parsers

## First Attempt

- functions of type `'t list -> ('a * 't list)`
- e.g., `digit ['1';'2']` results in `('1', ['2'])`
- but what about **errors**, i.e, `digit ['x';'y'] = ?`

# Parsers

## First Attempt

- functions of type `'t list -> ('a * 't list)`
- e.g., `digit ['1';'2']` results in `('1', ['2'])`
- but what about errors, i.e. `digit ['x';'y'] = ?`

## Type of Parsers

```
type ('a,'t)t = 't list -> ('a * 't list)option
```

- a parser works on a list of tokens of arbitrary type `'t`
- a successful parse yields `Some(x,ts)`
  - ➔ result `x` and remaining tokens `ts`
- a parse error is represented by `None`
  - ➔ no further information about the error

# Overview

- Week 9 - Combinator Parsing
  - Summary of Week 8
  - Motivation
  - **Combinator Parsing**
  - Parsing Simple Arithmetic Expressions

# Preparation

## Applying a Parser

```
let test p s = match p (Strng.of_string s) with
  | None       -> failwith "parse_error"
  | Some (x,ts) -> (x,ts)
```

# Preparation

## Applying a Parser

```
let test p s = match p (Strng.of_string s) with
  | None       -> failwith "parse_error"
  | Some (x,ts) -> (x,ts)
```

## Example

- `letter ...` parses a single letter

# Preparation

## Applying a Parser

```
let test p s = match p (Strng.of_string s) with
  | None      -> failwith "parse_error"
  | Some (x,ts) -> (x,ts)
```

## Example

- `letter ...` parses a single letter

```
# test letter "hello_world"
- char * char list = ('h', "ello_world")
# test letter "1234"
Exception: Failure "parse_error".
```

# Preparation

## Applying a Parser

```
let test p s = match p (Strng.of_string s) with
| None      -> failwith "parse_error"
| Some (x,ts) -> (x,ts)
```

## Example

- `letter ...` parses a single letter

```
# test letter "hello_world"
- char * char list = ('h', "ello_world")
# test letter "1234"
Exception: Failure "parse_error".
```
- `digit ...` parses a single digit

# Preparation

## Applying a Parser

```
let test p s = match p (Strng.of_string s) with
| None      -> failwith "parse_error"
| Some (x,ts) -> (x,ts)
```

## Example

- `letter ...` parses a single letter

```
# test letter "hello_world"
- char * char list = ('h', "ello_world")
# test letter "1234"
Exception: Failure "parse_error".
```
- `digit ...` parses a single digit

```
# test digit "1234"
- char * char list = ('1', "234")
```

# Preparation (cont'd)

## Type of a Parser

- type of parser:

```
type ('a,'t)t = 't list -> ('a * 't list)option
```

- often we want to process single tokens only, i.e.,  $f : 't \rightarrow 'a$
- `token` lifts `f` to parser, i.e., `token f : ('a,'t)t`

# Preparation (cont'd)

## Type of a Parser

- type of parser:

```
type ('a,'t)t = 't list -> ('a * 't list)option
```

- often we want to process single tokens only, i.e.,  $f : 't \rightarrow 'a$
- `token` lifts  $f$  to parser, i.e., `token f : ('a,'t)t`

## Operating on a Single Token

```
let token f = function  
  | []      -> None  
  | t::ts  -> match f t with  
    | Some x -> Some (x,ts)  
    | None   -> None
```

# Primitive Parsers

## Any Token Satisfying a Condition

```
let sat p ts = token(fun t -> if p t then Some t else None) ts
```

# Primitive Parsers

## Any Token Satisfying a Condition

```
let sat p ts = token(fun t -> if p t then Some t else None) ts
```

## Checking for End of Input

```
let eoi = function [] -> Some ((), [])  
             | _ -> None
```

# Primitive Parsers

## Any Token Satisfying a Condition

```
let sat p ts = token(fun t -> if p t then Some t else None) ts
```

## Checking for End of Input

```
let eoi = function [] -> Some ((),[])  
           | _ -> None
```

## Example

```
# test (sat ((=) 'h')) "hello_world"  
- char * char list = ('h', "ello_world")  
# test (sat ((=) 'e')) "hello_world"  
Exception Failure "parse_error".  
# test eoi ""  
- : unit * char list = ((), "")
```

# Character Parsers

## Reading a Given Character

```
let any ts = sat (fun _ -> true) ts
```

```
let char c ts = sat ((=) c) ts
```

# Character Parsers

## Reading a Given Character

```
let any ts = sat (fun _ -> true) ts

let char c ts = sat ((=) c) ts
```

## Reading Letters and Digits

```
let letter =
  sat(fun c -> ('a' <= c && c <= 'z') || ('A' <= c && c <= 'Z'))

let digit = sat (fun c -> '0' <= c && c <= '9')
```

# Character Parsers (cont'd)

## Choosing From a List of Tokens

```
let oneof s = sat (fun c -> Lst.mem c (Strng.of_string s))
```

## Character Parsers (cont'd)

### Choosing From a List of Tokens

```
let oneof s = sat (fun c -> Lst.mem c (Strng.of_string s))
```

### Every Token Except a Given List

```
let noneof s = sat (fun c -> not(Lst.mem c (Strng.of_string s)))
```

# Character Parsers (cont'd)

## Choosing From a List of Tokens

```
let oneof s = sat (fun c -> Lst.mem c (Strng.of_string s))
```

## Every Token Except a Given List

```
let noneof s = sat (fun c -> not(Lst.mem c (Strng.of_string s)))
```

## White Space

```
let space = oneof " \n\r\t"
```

# Character Parsers (cont'd)

## Choosing From a List of Tokens

```
let oneof s = sat (fun c -> Lst.mem c (Strng.of_string s))
```

## Every Token Except a Given List

```
let noneof s = sat (fun c -> not(Lst.mem c (Strng.of_string s)))
```

## White Space

```
let space = oneof "\n\r\t"
```

## Example

```
# test space "   hello_world"  
- : char * char list = (' ', "hello_world")
```

# Parser Combinators

## Choice

```
('a,'t)t -> ('a,'t)t -> ('a,'t)t
```

```
let (<|>) p q ts = match p ts with None          -> q ts  
                        | Some _ as r -> r
```

- choice takes two parsers `p` and `q` of same result type
- if `p` is successful on `ts` then its result is returned
- otherwise `q` is applied on `ts`

# Parser Combinators

## Choice

```
('a,'t)t -> ('a,'t)t -> ('a,'t)t
```

```
let (<|>) p q ts = match p ts with None          -> q ts
                    | Some _ as r -> r
```

- choice takes two parsers `p` and `q` of same result type
- if `p` is successful on `ts` then its result is returned
- otherwise `q` is applied on `ts`

## Example

```
# test (letter <|> digit) "hello_world"
- : char * char list = ('h', "hello_world")
# test (letter <|> digit) "1234"
- : char * char list = ('1', "234")
```

# Parser Combinators (cont'd)

## Bind - Binding a Parser to the Result of Another

```
('a,'t)t -> ('a -> ('b,'t)t) -> ('b,'t)t
```

```
let (>>=) p f ts = match p ts with None      -> None
                        | Some(x,ts) -> f x ts
```

- bind takes two arguments
- first a parser `p` with results of type `'a`
- then a function `f` taking an `'a` and producing a parser with results of type `'b`
- `p >>= f` executes `p` and then feeds the function `f` with its result
- since `f x` is a parser, the result of `p >>= f` is a parser

# Parser Combinators (cont'd)

## Then - Sequential Composition of Parsers

```
('a,'t)t -> ('b,'t)t -> ('b,'t)t
```

```
let (>>) p q ts = (>>=) p (fun _ -> q) ts
```

- then takes two parsers `p` and `q`
- first a parser `p` with results of type `'a`
- then a parser `q` with result type `'b`
- `p >> q` first executes `p` and then executes `q`
- the result of `p` is ignored, the result of `q` is returned

# Parser Combinators (cont'd)

## Then - Sequential Composition of Parsers

`('a,'t)t -> ('b,'t)t -> ('b,'t)t`

`let (>>) p q ts = (>>=) p (fun _ -> q) ts`

- then takes two parsers `p` and `q`
- first a parser `p` with results of type `'a`
- then a parser `q` with result type `'b`
- `p >> q` first executes `p` and then executes `q`
- the result of `p` is ignored, the result of `q` is returned

## Example

```
# test (space >> space) "   hello   world"
- : char * char list = (' ', "hello world")
```

# Turning Values Into Parsers

## Return

```
'a -> ('a,'t)t
```

```
let return x = fun ts -> Some (x,ts)
```

- `return x` takes the value `x` and yields a parser that returns `x` without consuming any input

# Turning Values Into Parsers

## Return

```
'a -> ('a,'t)t
```

```
let return x = fun ts -> Some (x,ts)
```

- `return x` takes the value `x` and yields a parser that returns `x` without consuming any input

## Example

```
# test (return 3) "hello_world"
```

```
- : int * char list = (3, "hello_world")
```

# Counting Spaces

## First try

```
let rec count_spaces =  
  (space >>  
    count_spaces >>= fun i -> return (i+1))  
<|>  
  (any >>  
    count_spaces >>= fun i -> return i)  
<|>  
  (eoi >> return 0)
```

# Counting Spaces

## First try

```
let rec count_spaces =  
  (space >>  
    count_spaces >>= fun i -> return (i+1))  
<|>  
  (any >>  
    count_spaces >>= fun i -> return i)  
<|>  
  (eoi >> return 0)
```

## Problem

- OCaml interpreter detects that `count_spaces` would not terminate (eager evaluation)
- Error: This kind of expression is not allowed as right-hand ...

# Counting Spaces (cont'd)

## Second try (dummy argument)

```
let rec count_spaces () =  
  (space >>  
    count_spaces () >>= fun i -> return (i+1))  
<|>  
  (any >>  
    count_spaces () >>= fun i -> return i)  
<|>  
  (eoi >> return 0)
```

# Counting Spaces (cont'd)

## Second try (dummy argument)

```
let rec count_spaces () =  
  (space >>  
    count_spaces () >>= fun i -> return (i+1))  
<|>  
  (any >>  
    count_spaces () >>= fun i -> return i)  
<|>  
  (eoi >> return 0)
```

## Problem

- OCaml interpreter doesn't detect nontermination (eager evaluation)
- `# test (count_spaces ()) "hello_world"`  
Stack overflow during evaluation (looping recursion?).

## Counting Spaces (cont'd)

### Third try (enforce evaluation)

```
let rec count_spaces () =  
  (space >>= fun _ ->  
    count_spaces () >>= fun i -> return (i+1))  
<|>  
  (any >>= fun _ ->  
    count_spaces () >>= fun i -> return i)  
<|>  
  (eoi >> return 0)
```

## Counting Spaces (cont'd)

### Third try (enforce evaluation)

```
let rec count_spaces () =  
  (space >>= fun _ ->  
    count_spaces () >>= fun i -> return (i+1))  
<|>  
  (any >>= fun _ ->  
    count_spaces () >>= fun i -> return i)  
<|>  
  (eoi >> return 0)
```

### Success

```
# test (count_spaces ()) "hello_world"  
- : int * char list = (1, "")  
# test (count_spaces ()) "   hello_world"  
- : int * char list = (4, "")
```

# Parser Combinators (cont'd)

## Many

```
let rec many p = (  
  p      >>= fun x ->  
  many p >>= fun xs ->  
    return (x::xs)  
) <|> return []
```

- `many p` applies `p` **zero** or more times
- result is list of results of `p`
- greedy (as many applications of `p` as possible)

# Parser Combinators (cont'd)

## Many

```
let rec many p = (  
  p      >>= fun x ->  
  many p >>= fun xs ->  
    return (x::xs)  
) <|> return []
```

- `many p` applies `p` zero or more times
- result is list of results of `p`
- greedy (as many applications of `p` as possible)

## Example

```
# test (many space) "   hello_world"  
- : char list * char list = ("   ", "hello_world")
```

# Overview
