#### Abstract

The dependency pair approach $[2,12,13]$ is one of the most powerful techniques for termination and innermost termination proofs of term rewrite systems (TRSs). For any TRS, it generates inequality constraints that have to be satisfied by weakly monotonic well-founded orders. We improve the dependency pair approach by considerably reducing the number of constraints produced for (innermost) termination proofs. Moreover, we extend transformation techniques to manipulate dependency pairs which simplify (innermost) termination proofs significantly. In order to fully automate the dependency pair approach, we show how transformation techniques and the search for suitable orders can be mechanized efficiently. We implemented our results in the automated termination prover AProVE and evaluated them on large collections of examples.

## 1 Introduction

Termination is an essential property of term rewrite systems. Most traditional methods to prove termination of TRSs (automatically) use simplification orders $[8,28]$, where a term is greater than its proper subterms (subterm property). Examples for simplification orders include lexicographic or recursive path orders [7, 19], the Knuth-Bendix order [20], and (most) polynomial orders [22]. However, there are numerous important TRSs which are not simply terminating, i.e., their termination cannot be shown by simplification orders. Therefore, the dependency pair approach $[2,12,13]$ was developed which allows the application of simplification orders to non-simply terminating TRSs. In this way, the class of systems where termination is provable mechanically increases significantly.

Example 1 The following TRS from [2] is not simply terminating, since in the last quot-rule, the left-hand side is embedded in the right-hand side if $y$ is instantiated with $\mathbf{s}(x)$. Thus, classical approaches for automated termination proofs fail on this example, while it is easy to handle with dependency pairs.

$$
\begin{aligned}
\operatorname{minus}(x, 0) & \rightarrow x \\
\operatorname{minus}(\mathrm{~s}(x), \mathrm{s}(y)) & \rightarrow \operatorname{minus}(x, y) \\
\operatorname{quot}(0, \mathrm{~s}(y)) & \rightarrow 0 \\
\text { quot }(\mathrm{s}(x), \mathrm{s}(y)) & \rightarrow \mathbf{s}(\text { quot }(\operatorname{minus}(x, y), \mathrm{s}(y)))
\end{aligned}
$$

[^0]In Sect. 2, we recapitulate the dependency pair approach for termination and innermost termination proofs (i.e., one tries to show that all reductions are finite, where in the innermost termination case, one only considers reductions of innermost redexes). Then we present new results which show that the approach can be improved significantly by reducing the constraints for termination (Sect. 3) and innermost termination (Sect. 4). Sect. 5 introduces new conditions for transforming dependency pairs by narrowing, rewriting, and instantiation in order to simplify (innermost) termination proofs further.

For automated (innermost) termination proofs, the constraints generated by the dependency pair approach are pre-processed by an argument filtering and afterwards, one tries to solve them by standard simplification orders. We present an algorithm to generate argument filterings in our improved dependency pair approach (Sect. 6) and discuss heuristics to increase efficiency in Sect. 7.

Our improvements and algorithms are implemented in our termination prover AProVE. We give empirical results which show that they are extremely successful in practice. Details on our experiments can be found in the appendix. Thus, the contributions of this paper are also very helpful for other tools based on dependency pairs (e.g., [1], CiME [6], TTT [17]). Moreover, we conjecture that they can also be used in other recent approaches for termination [5,11] which have several aspects in common with dependency pairs. Finally, dependency pairs can be combined with other termination techniques (e.g., in [29] we integrated dependency pairs and the size-change principle from termination analysis of functional [23] and logic programs [10]). Moreover, the system TALP [26] uses dependency pairs for termination proofs of logic programs. Thus, improving dependency pairs is also useful for termination analysis of other kinds of programming languages.

## 2 Dependency Pairs

We briefly present the dependency pair approach of Arts and Giesl and refer to $[2,12,13]$ for refinements and motivations. We assume familiarity with term rewriting (see, e.g., [4]). For a $\operatorname{TRS} \mathcal{R}$ over a signature $\mathcal{F}$, the defined symbols $\mathcal{D}$ are the root symbols of the left-hand sides of rules and the constructors are $\mathcal{C}=\mathcal{F} \backslash \mathcal{D}$. We restrict ourselves to finite signatures and TRSs. Let $\mathcal{F}^{\sharp}=\left\{f^{\sharp} \mid\right.$ $f \in \mathcal{D}\}$ be a set of tuple symbols, where $f^{\sharp}$ has the same arity as $f$ and we often write $F$ for $f^{\sharp}$, etc. If $t=g\left(t_{1}, \ldots, t_{m}\right)$ with $g \in \mathcal{D}$, we write $t^{\sharp}$ for $g^{\sharp}\left(t_{1}, \ldots, t_{m}\right)$.

Definition 2 (Dependency Pair) If $l \rightarrow r \in \mathcal{R}$ and $t$ is a subterm of $r$ with defined root symbol, then the rewrite rule $l^{\sharp} \rightarrow t^{\sharp}$ is called a dependency pair of $\mathcal{R}$. The set of all dependency pairs of $\mathcal{R}$ is denoted by $D P(\mathcal{R})$.

So the dependency pairs of the TRS in Ex. 1 are

$$
\begin{align*}
\operatorname{MINUS}(\mathrm{s}(x), \mathrm{s}(y)) & \rightarrow \operatorname{MINUS}(x, y)  \tag{1}\\
\operatorname{QUOT}(\mathrm{s}(x), \mathrm{s}(y)) & \rightarrow \operatorname{MINUS}(x, y)  \tag{2}\\
\operatorname{QUOT}(\mathrm{s}(x), \mathrm{s}(y)) & \rightarrow \operatorname{QUOT}(\operatorname{minus}(x, y), \mathbf{s}(y)) \tag{3}
\end{align*}
$$

To use dependency pairs for (innermost) termination proofs, we need the notion of (innermost) chains. We always assume that different occurrences of dependency pairs are variable disjoint and we always consider substitutions whose domains may be infinite. Here, $\xrightarrow{i}_{\mathcal{R}}$ denotes innermost reductions.

Definition 3 ( $\mathcal{R}$-Chain) A sequence of dependency pairs $s_{1} \rightarrow t_{1}, s_{2} \rightarrow t_{2}, \ldots$ is an $\mathcal{R}$-chain if there exists a substitution $\sigma$ such that $t_{j} \sigma \rightarrow_{\mathcal{R}}^{*} s_{j+1} \sigma$ for every two consecutive pairs $s_{j} \rightarrow t_{j}$ and $s_{j+1} \rightarrow t_{j+1}$ in the sequence. Such a chain is an innermost $\mathcal{R}$-chain if $t_{j} \sigma \xrightarrow{i}{ }_{\mathcal{R}}^{*} \sigma$ and if $s_{j} \sigma$ is a normal form for all $j$.

Now we obtain the following sufficient and necessary criterion for termination and innermost termination.

Theorem 4 (Termination Criterion [2]) $\mathcal{R}$ terminates iff there is no infinite chain. $\mathcal{R}$ is innermost terminating iff there is no infinite innermost chain.

To estimate which dependency pairs may occur consecutively in (innermost) chains, one builds a so-called (innermost) dependency graph whose nodes are the dependency pairs and there is an arc from $v \rightarrow w$ to $s \rightarrow t$ iff $v \rightarrow w, s \rightarrow t$ is an (innermost) chain. In our example, the dependency graph and the innermost dependency graph have the $\operatorname{arcs}(1) \Rightarrow(1),(2) \Rightarrow(1),(3) \Rightarrow(2)$, and $(3) \Rightarrow(3)$.

Since it is undecidable whether two dependency pairs form an (innermost) chain, we construct estimated graphs such that all cycles in the real graph are also cycles in the estimated graph. Let $\operatorname{CAP}(t)$ result from replacing all variables and all subterms of $t$ that have a defined root symbol by different fresh variables. Here, multiple occurrences of the same variable are replaced by the same fresh variable, but multiple occurrences of the same subterm with defined root are replaced by pairwise different fresh variables. Let $\operatorname{REN}(t)$ result from replacing all occurrences of variables in $t$ by different fresh variables (i.e., $\operatorname{REN}(t)$ is a linear term). For instance, $\operatorname{CAP}(\operatorname{QUOT}(\operatorname{minus}(x, y), \mathrm{s}(y)))=\operatorname{QUOT}\left(z, \mathrm{~s}\left(y_{1}\right)\right), \operatorname{CAP}(\operatorname{QUOT}(x, x))=$ $\operatorname{QUOT}\left(x_{1}, x_{1}\right)$, and REn $(\operatorname{QUOT}(x, x))=\operatorname{QUOT}\left(x_{1}, x_{2}\right)$. We define CAP $v$ like cap except that subterms with defined root that already occur in $v$ are not replaced by new variables.

Definition 5 (Estimated (innermost) dependency graph) The estimated dependency graph of a TRS $\mathcal{R}$ is the directed graph whose nodes are the dependency pairs and there is an arc from $v \rightarrow w$ to $s \rightarrow t$ iff $\operatorname{REN}(\operatorname{CAP}(w))$ and $s$ are unifiable. In the estimated innermost dependency graph there is an arc from $v \rightarrow w$ to $s \rightarrow t$ iff $\operatorname{CAP}_{v}(w)$ and $s$ are unifiable by a most general unifier (mgu) $\mu$ such that $v \mu$ and $s \mu$ are in normal form.

In Ex. 1, the estimated dependency graph and the estimated innermost dependency graph are identical to the real dependency graph. Alternative approximations of dependency graphs can be found in [16, 24].

A set $\mathcal{P} \neq \varnothing$ of dependency pairs is called a cycle if for any two pairs $v \rightarrow w$ and $s \rightarrow t$ in $\mathcal{P}$ there is a non-empty path from $v \rightarrow w$ to $s \rightarrow t$ in the graph which
only traverses pairs from $\mathcal{P}$. In our example, we have the cycles $\mathcal{P}_{1}=\{(1)\}$ and $\mathcal{P}_{2}=\{(3)\}$. Since we only regard finite TRSs, any infinite (innermost) chain of dependency pairs corresponds to a cycle in the (innermost) dependency graph.

To show (innermost) termination of TRSs, one proves absence of infinite (innermost) chains separately for every cycle. To this end, one generates sets of constraints which should be satisfied by some reduction pair $(\succsim, \succ)$ [21] consisting of a quasi-rewrite order $\succsim$ (i.e., $\succsim$ is reflexive, transitive, monotonic (closed under contexts), stable (closed under substitutions)) and a stable well-founded order $\succ$ which is compatible with $\succsim$ (i.e., $\succsim \circ \succ \subseteq \succ$ and $\succ \circ \succsim \subseteq \succ$ ). Note that $\succ$ need not be monotonic. Essentially, the constraints for termination of a cycle $\mathcal{P}$ ensure that all rewrite rules and all dependency pairs in $\mathcal{P}$ are weakly decreasing (w.r.t. $\succsim$ ) and at least one dependency pair in $\mathcal{P}$ is strictly decreasing (w.r.t. $\succ$ ). For innermost termination, only the usable rules have to be weakly decreasing. In Ex. 1, the usable rules for $\mathcal{P}_{1}$ are empty and the usable rules for $\mathcal{P}_{2}$ are the minus-rules.

Definition 6 (Usable Rules) For $f \in \mathcal{F}$, let $R l s(f)=\{l \rightarrow r \in \mathcal{R} \mid \operatorname{root}(l)=$ $f\}$. For any term, the usable rules are the smallest set of rules such that

- $\mathcal{U}(x)=\varnothing$ for $x \in \mathcal{V}$ and
- $\mathcal{U}\left(f\left(t_{1}, \ldots, t_{n}\right)\right)=R l s(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r) \cup \bigcup_{j=1}^{n} \mathcal{U}\left(t_{j}\right)$.

Moreover, for any set $\mathcal{P}$ of dependency pairs, we define $\mathcal{U}(\mathcal{P})=\bigcup_{s \rightarrow t \in \mathcal{P}} \mathcal{U}(t)$.
We want to use standard techniques to synthesize reduction pairs satisfying the constraints of the dependency pair approach. Most existing techniques generate monotonic orders $\succ$. However, for the dependency pair approach we only need a monotonic quasi-order $\succsim$, whereas $\succ$ does not have to be monotonic. (This is often called "weak monotonicity".) For that reason, before synthesizing a suitable order, some of the arguments of function symbols can be eliminated. To perform this elimination of arguments resp. of function symbols the concept of argument filtering was introduced in [2] (here we use the notation of [21]).

Definition 7 (Argument Filtering) An argument filtering $\pi$ for a signature $\mathcal{F}$ maps every $n$-ary function symbol to an argument position $i \in\{1, \ldots, n\}$ or to a (possibly empty) list $\left[i_{1}, \ldots, i_{m}\right]$ of argument positions with $1 \leq i_{1}<\ldots$ $<i_{m} \leq n$. The signature $\mathcal{F}_{\pi}$ consists of all function symbols $f$ such that $\pi(f)=$ $\left[i_{1}, \ldots, i_{m}\right]$, where in $\mathcal{F}_{\pi}$ the arity of $f$ is $m$. Every argument filtering $\pi$ induces a mapping from $\mathcal{T}(\mathcal{F}, \mathcal{V})$ to $\mathcal{T}\left(\mathcal{F}_{\pi}, \mathcal{V}\right)$, also denoted by $\pi$, which is defined as:

$$
\pi(t)= \begin{cases}t & \text { if } t \text { is a variable } \\ \pi\left(t_{i}\right) & \text { if } t=f\left(t_{1}, \ldots, t_{n}\right) \text { and } \pi(f)=i \\ f\left(\pi\left(t_{i_{1}}\right), \ldots, \pi\left(t_{i_{m}}\right)\right) & \text { if } t=f\left(t_{1}, \ldots, t_{n}\right) \text { and } \pi(f)=\left[i_{1}, \ldots, i_{m}\right]\end{cases}
$$

An argument filtering with $\pi(f)=i$ for some $f \in \mathcal{F}$ is called collapsing.
Now the technique of automating dependency pairs can be formulated as follows. Here, we always use argument filterings for the signature $\mathcal{F} \cup \mathcal{F} \sharp$.

Theorem 8 (Automating Dependency Pairs [2,13]) A TRS $\mathcal{R}$ is terminating iff for any cycle $\mathcal{P}$ of the (estimated) dependency graph, there is a reduction pair $(\succsim, \succ)$ and an argument filtering $\pi$ such that both
(a) $\pi(s) \succ \pi(t)$ for one dependency pair $s \rightarrow t$ from $\mathcal{P}$ and $\pi(s) \succsim \pi(t)$ or $\pi(s) \succ \pi(t)$ for all other dependency pairs $s \rightarrow t$ from $\mathcal{P}$
(b) $\pi(l) \succsim \pi(r)$ for all $l \rightarrow r \in \mathcal{R}$
$\mathcal{R}$ is innermost terminating if for any cycle $\mathcal{P}$ of the (estimated) innermost dependency graph, there is a reduction pair $(\succsim, \succ)$ and an argument filtering $\pi$ with both
(c) $\pi(s) \succ \pi(t)$ for one dependency pair $s \rightarrow t$ from $\mathcal{P}$ and
$\pi(s) \succsim \pi(t)$ or $\pi(s) \succ \pi(t)$ for all other dependency pairs $s \rightarrow t$ from $\mathcal{P}$
(d) $\pi(l) \succsim \pi(r)$ for all $l \rightarrow r \in \mathcal{U}(\mathcal{P})$

So in Ex. 1, we obtain the following constraints for termination. Here, $\left(\succsim_{i}, \succ_{i}\right)$ is the reduction pair and $\pi_{i}$ is the argument filtering for cycle $\mathcal{P}_{i}$, where $i \in\{1,2\}$.

$$
\begin{align*}
\pi_{1}(\operatorname{MINUS}(\mathrm{~s}(x), \mathrm{s}(y))) & \succ_{1} \pi_{1}(\operatorname{MINUS}(x, y))  \tag{4}\\
\pi_{2}(\operatorname{QUOT}(\mathrm{~s}(x), \mathrm{s}(y))) & \succ_{2} \pi_{2}(\operatorname{QUOT}(\operatorname{minus}(x, y), \mathrm{s}(y)))  \tag{5}\\
\pi_{i}(\operatorname{minus}(x, 0)) & \succsim_{i} \pi_{i}(x)  \tag{6}\\
\pi_{i}(\operatorname{minus}(\mathrm{~s}(x), \mathrm{s}(y))) & \succsim_{i} \pi_{i}(\operatorname{minus}(x, y))  \tag{7}\\
\pi_{i}(\operatorname{quot}(0, \mathrm{~s}(y))) & \succsim_{i} \pi_{i}(0)  \tag{8}\\
\pi_{i}(\operatorname{quot}(\mathrm{~s}(x), \mathrm{s}(y))) & \succsim_{i} \pi_{i}(\mathrm{~s}(\operatorname{quot}(\operatorname{minus}(x, y), \mathrm{s}(y)))) \tag{9}
\end{align*}
$$

The filtering $\pi_{i}$ (minus) $=$ [1] replaces all terms $\operatorname{minus}\left(t_{1}, t_{2}\right)$ by minus $\left(t_{1}\right)$. With this filtering, (4)-(9) are satisfied by the lexicographic path order (LPO) with the precedence quot $>s>$ minus. Thus, termination of this TRS is proved.

For innermost termination, we only obtain the constraint (4) for the cycle $\mathcal{P}_{1}$, since it has no usable rules. For $\mathcal{P}_{2}$, the constraints (8) and (9) are not necessary, since the quot-rules are not usable for any right-hand side of a dependency pair. In general, the constraints for innermost termination are always a subset of the constraints for termination. Thus, for classes of TRSs where innermost termination already implies termination (e.g., non-overlapping TRSs) [14], one should always use the approach for innermost termination when attempting termination proofs.

As shown in [16], to implement Thm. 8, one should not compute all cycles, but only maximal cycles (strongly connected components (SCCs)) that are not contained in other cycles. When solving the constraints of Thm. 8 for an SCC, the strict constraint $\pi(s) \succ \pi(t)$ may be satisfied for several dependency pairs $s \rightarrow t$ in the SCC. Thus, subcycles of the SCC containing such a strictly decreasing dependency pair do not have to be considered anymore. So after solving the constraints for the initial SCCs, all strictly decreasing dependency pairs are removed and one now builds SCCs from the remaining dependency pairs, etc.

## 3 Improved Termination Proofs

Now the technique of Thm. 8 for automated termination proofs is improved. For automation, one usually uses a quasi-simplification order $\succsim$ (i.e., a monotonic, stable quasi-order with $f(\ldots t \ldots) \succsim t$ for any term $t$ and symbol $f$ ). As observed in [25], then the constraints (a) and (b) of Thm. 8 even imply $C_{\varepsilon}$-termination of $\mathcal{R}$. A TRS $\mathcal{R}$ is $C_{\varepsilon}$-terminating iff $\mathcal{R} \cup\{c(x, y) \rightarrow x, c(x, y) \rightarrow y\}$ is terminating where $c$ is a fresh function symbol not occurring in $\mathcal{R}$. Urbain showed in [31] how to use dependency pairs for modular termination proofs of hierarchical combinations of $C_{\varepsilon}$-terminating TRSs. However in the results of [31], he did not integrate the consideration of cycles in (estimated) dependency graphs and required all dependency pairs to be strictly decreasing. Thm. 9 extends his modularity results by combining them with cycles. In this way, one obtains an improvement for termination proofs with dependency pairs which can be used for TRSs in general. The advantage is that the set of constraints (b) in Thm. 8 is reduced significantly.

The crucial idea of [31] is to consider the recursion hierarchy of function symbols. A function symbol $f$ depends on the symbol $h$ (denoted $f \geq_{d} h$ ) if $f=h$ or if there exists a symbol $g$ such that $g$ occurs in an $f$-rule and $g$ depends on $h$. We define $>_{d}=\geq_{d} \backslash \leq_{d}$ and $\sim_{d}=\geq_{d} \cap \leq_{d}$. So $f \sim_{d} g$ means that $f$ and $g$ are mutually recursive. If $\mathcal{R}=\mathcal{R}_{1} \uplus \ldots \uplus \mathcal{R}_{n}$ and $f \sim_{d} g$ iff $R l s(f) \cup R l s(g) \subseteq \mathcal{R}_{i}$, then we call $\mathcal{R}_{1}, \ldots, \mathcal{R}_{n}$ a separation of $\mathcal{R}$. Moreover, we extend $\geq_{d}$ to the sets $\mathcal{R}_{i}$ by defining $\mathcal{R}_{i} \geq_{d} \mathcal{R}_{j}$ iff $f \geq_{d} g$ for all $f, g$ with $\operatorname{Rls}(f) \subseteq \mathcal{R}_{i}$ and $\operatorname{Rls}(g) \subseteq \mathcal{R}_{j}$. For any $i$, let $\mathcal{R}_{i}^{\prime}$ denote the rules that $\mathcal{R}_{i}$ depends on, i.e., $\mathcal{R}_{i}^{\prime}=\bigcup_{\mathcal{R}_{i} \geq d} \mathcal{R}_{j} \mathcal{R}_{j}$.

It is clear that any cycle can only consist of dependency pairs from one $\mathcal{R}_{i}$. Thus, in Thm. 8 we only have to regard cycles $\mathcal{P}$ with dependency pairs from $D P\left(\mathcal{R}_{i}\right)$. However, to detect the cycles $\mathcal{P}$, we still have to regard the dependency graph of the whole TRS $\mathcal{R}$. The reason is that we have to consider $\mathcal{R}$-chains, not just $\mathcal{R}_{i}$ - or $\mathcal{R}_{i}^{\prime}$-chains. ${ }^{1}$

Thm. 9 states that instead of requiring $\pi(l) \succsim \pi(r)$ for all rules $l \rightarrow r$ of $\mathcal{R}$, it suffices to demand it only for rules that $\mathcal{R}_{i}$ depends on, i.e., for rules from $\mathcal{R}_{i}^{\prime}$. So in the termination proof of Ex. $1, \pi(l) \succsim \pi(r)$ does not have to be required for the quot-rules when regarding the cycle $\mathcal{P}_{1}=\{\operatorname{MINUS}(\mathrm{s}(x), \mathrm{s}(y)) \rightarrow \operatorname{MINUS}(x, y)\}$. However, this improvement is sound only if $\succsim$ is a quasi-simplification order. ${ }^{2}$

Theorem 9 (Improved Termination Proofs with DPs) Let $\mathcal{R}_{1}, \ldots, \mathcal{R}_{n}$ be $a$ separation of $\mathcal{R}$. The TRS $\mathcal{R}$ is terminating if for all $1 \leq i \leq n$ and any cycle $\mathcal{P}$ of the (estimated) dependency graph of $\mathcal{R}$ with $\mathcal{P} \subseteq D P\left(\mathcal{R}_{i}\right)$, there is a reduction pair $(\succsim, \succ)$ where $\succsim$ is a quasi-simplification order and an argument filtering $\pi$ such that both

[^1](a) $\pi(s) \succ \pi(t)$ for one dependency pair $s \rightarrow t$ from $\mathcal{P}$ and $\pi(s) \succsim \pi(t)$ or $\pi(s) \succ \pi(t)$ for all other dependency pairs $s \rightarrow t$ from $\mathcal{P}$
(b) $\pi(l) \succsim \pi(r)$ for all $l \rightarrow r \in \mathcal{R}_{i}^{\prime}$

Proof. We prove that (a) and (b) imply termination of $\mathcal{R}$. If $\mathcal{R}$ is not terminating, then by Thm. 4 there exists an infinite chain $s_{1} \rightarrow t_{1}, s_{2} \rightarrow t_{2}, \ldots$ of dependency pairs where $t_{j} \sigma \rightarrow_{\mathcal{R}}^{*} s_{j+1} \sigma$ for all $j$. As can be seen from the proof of Thm. 4 in $[2, \mathrm{Thm} .6]$, the infinite chain and the substitution can be chosen in such a way that all $s_{j} \sigma$ and $t_{j} \sigma$ are terminating.

Without loss of generality, these dependency pairs come from a cycle $\mathcal{P}$ of the dependency graph of $\mathcal{R}$ where $\mathcal{P} \subseteq D P\left(\mathcal{R}_{i}\right)$. Let $\mathcal{R}_{i}^{\prime \prime}=\mathcal{R} \backslash \mathcal{R}_{i}^{\prime}$. Then $\mathcal{R}_{i}^{\prime}$ and $\mathcal{R}_{i}^{\prime \prime}$ form a hierarchical combination (thus, defined symbols of $\mathcal{R}_{i}^{\prime}$ may occur as constructors in $\mathcal{R}_{i}^{\prime \prime}$, but not vice versa). By [31, Lemma 2] there exists a substitution $\sigma^{\prime}$ such that $t_{j} \sigma^{\prime} \rightarrow_{\mathcal{R}_{i \varepsilon}^{\prime}}^{*} s_{j+1} \sigma^{\prime}$, where $\mathcal{R}_{i \varepsilon}^{\prime}=\mathcal{R}_{i}^{\prime} \cup\{c(x, y) \rightarrow x, c(x, y) \rightarrow y\}$. Since $\succsim$ is a quasi-simplification order with $\pi(l) \succsim \pi(r)$ for all $l \rightarrow r \in \mathcal{R}_{i}^{\prime}$ by Constraint (b), we obtain $\pi\left(t_{j} \sigma^{\prime}\right)=\pi\left(t_{j}\right) \sigma_{\pi}^{\prime} \succsim \pi\left(s_{j+1}\right) \sigma_{\pi}^{\prime}=\pi\left(s_{j+1} \sigma^{\prime}\right)$ where $\sigma_{\pi}^{\prime}(x)=\pi\left(\sigma^{\prime}(x)\right)$ for all $x \in \mathcal{V}$. Note that here we also need $c(x, y) \succsim x$ and $c(x, y) \succsim y$, which holds for all quasi-simplification orders. Constraint (a) implies $\pi\left(s_{j}\right) \sigma_{\pi}^{\prime} \succ \pi\left(t_{j}\right) \sigma_{\pi}^{\prime}$ for infinitely many $j$ and $\pi\left(s_{j}\right) \sigma_{\pi}^{\prime} \succsim \pi\left(t_{j}\right) \sigma_{\pi}^{\prime}$ for all remaining $j$. Thus, by compatibility of $\succsim$ and $\succ$ we obtain a contradiction to the wellfoundedness of $\succ$.

Example 10 This TRS of [27] shows that Thm. 9 not only increases efficiency , but also leads to a more powerful method. Here, $\operatorname{int}\left(\mathrm{s}^{n}(0), \mathrm{s}^{m}(0)\right)$ computes $\left[s^{n}(0), s^{n+1}(0), \ldots, s^{m}(0)\right]$, nil is the empty list, and cons represents list insertion.

$$
\begin{align*}
\operatorname{intlist}(\text { nil }) & \rightarrow \text { nil }  \tag{10}\\
\operatorname{intlist}(\operatorname{cons}(x, y)) & \rightarrow \operatorname{cons}(\mathrm{s}(x), \operatorname{intlist}(y))  \tag{11}\\
\operatorname{int}(0,0) & \rightarrow \operatorname{cons}(0, \mathrm{nil})  \tag{12}\\
\operatorname{int}(0, \mathrm{~s}(y)) & \rightarrow \operatorname{cons}(0, \operatorname{int}(\mathrm{~s}(0), \mathrm{s}(y)))  \tag{13}\\
\operatorname{int}(\mathrm{s}(x), 0) & \rightarrow \operatorname{nil}  \tag{14}\\
\operatorname{int}(\mathrm{s}(x), \mathrm{s}(y)) & \rightarrow \operatorname{intlist}(\operatorname{int}(x, y)) \tag{15}
\end{align*}
$$

The TRS is separated into the intlist-rules $\mathcal{R}_{1}$ and the int-rules $\mathcal{R}_{2}>{ }_{d} \mathcal{R}_{1}$. The constraints of Thm. 8 for termination of $\mathcal{P}=\{\operatorname{INTLIST}(\operatorname{cons}(x, y)) \rightarrow$ INTLIST $(y)\}$ cannot be solved with reduction pairs based on simplification orders:

We must satisfy $\pi(\operatorname{INTLIST}(\operatorname{cons}(x, y))) \succ \pi(\operatorname{INTLIST}(y))(*)$. We distinguish three cases. First, let $\pi(\mathrm{s}) \neq[]$ or $\pi(\mathrm{int})=[]$. Then we have $\pi(\operatorname{int}(0, \mathrm{~s}(y))) \succsim$ $\pi(\operatorname{cons}(0, \operatorname{int}(\mathrm{~s}(0), \mathrm{s}(y)))) \succsim \pi(\operatorname{cons}(0, \operatorname{int}(0, \mathrm{~s}(y))))$ by weak decreasingness of Rule (13) and the subterm property. When substituting $x$ by 0 and $y$ by $\operatorname{int}(0, \mathrm{~s}(y))$ in $(*)$, we obtain a contradiction to well-foundedness of $\succ$.

Next, let $\pi$ (intlist) $=$ []. Rule (11) implies intlist $\succsim \pi(\operatorname{cons}(\mathrm{s}(x)$, intlist(...))) which gives a similar contradiction when substituting $x$ by $\mathrm{s}(x)$ and $y$ by intlist(...) in ( $*$ ).

Finally, let $\pi(\mathrm{s})=[], \pi(\mathrm{int}) \neq[]$, and $\pi($ intlist $) \neq[]$. Now we obtain a contradiction, since the filtered rule (15) cannot be weakly decreasing. The reason is that $x$ or $y$ occur on its right-hand side, but not on its left-hand side.

In contrast, when using Thm. 9, only $\mathcal{R}_{1}^{\prime}=\mathcal{R}_{1}$ must be weakly decreasing when examining $\mathcal{P}$. These constraints are satisfied by the embedding order using an argument filtering with $\pi($ cons $)=[2], \pi($ intlist $)=\pi($ INTLIST $)=1, \pi(s)=[1]$.

The constraints from $\mathcal{R}_{2}$ 's cycle and rules from $\mathcal{R}_{2}^{\prime}=\mathcal{R}_{1} \cup \mathcal{R}_{2}$ can also be oriented (by LPO and a filtering with $\pi$ (cons) $=1$ and $\pi($ INT $)=2$ ). However, this part of the proof requires the consideration of cycles of the (estimated) dependency graph. The reason is that there is no argument filtering and simplification order such that both dependency pairs of $\mathcal{R}_{2}$ are strictly decreasing: $\pi(\operatorname{INT}(\mathbf{s}(x), \mathbf{s}(y))) \succ \pi(\operatorname{INT}(x, y))$ implies $\pi(\mathbf{s})=[1]$. But then $\pi(\operatorname{INT}(0, \mathbf{s}(y)))$ is embedded in $\pi(\operatorname{INT}(\mathrm{s}(0), \mathrm{s}(y)))$. Hence, we have $\pi(\operatorname{INT}(\mathrm{s}(0), \mathrm{s}(y))) \nsucc \pi(\operatorname{INT}(0$, $\mathbf{s}(y))$ ) for any simplification order $\succ$.

So if one only considers cycles or if one only uses Urbain's modularity result [31], then Ex. 10 fails with simplification orders. Instead, both refinements should be combined as in Thm. 9 .

## 4 Improved Innermost Termination Proofs

Proving innermost termination with dependency pairs is easier than proving termination for two reasons: the innermost dependency graph has less arcs than the dependency graph and we only require $l \succsim r$ for the usable rules instead of all rules. In Sect. 3 we showed that for termination, it suffices to require $l \succsim r$ only for the rules of $\mathcal{R}_{i}^{\prime}$ if the current cycle consists of $\mathcal{R}_{i}$-dependency pairs. Still, $\mathcal{R}_{i}^{\prime}$ is always a superset of the usable rules. Now we present a new improvement of Thm. 8 for innermost termination in order to reduce the set of usable rules.

The idea is to apply the argument filtering first and to determine the usable rules afterwards. However, for collapsing argument filterings this destroys the soundness of the technique. Consider the non-innermost terminating TRS

$$
\mathrm{f}(\mathrm{~s}(x)) \rightarrow \mathrm{f}(\operatorname{double}(x)) \quad \text { double }(0) \rightarrow 0 \quad \text { double }(\mathrm{s}(x)) \rightarrow \mathrm{s}(\mathrm{~s}(\text { double }(x)))
$$

In the cycle $\{\mathrm{F}(\mathrm{s}(x)) \rightarrow \mathrm{F}($ double $(x))\}$, we could use the argument filtering $\pi$ (double) $=1$ which results in $\{\mathrm{F}(\mathrm{s}(x)) \rightarrow \mathrm{F}(x)\}$. Since the filtered dependency pair contains no defined symbols, we would conclude that the cycle has no usable rules. Then, we could easily orient the only resulting constraint $\mathrm{F}(\mathrm{s}(x)) \succ \mathrm{F}(x)$ for this cycle and falsely prove innermost termination. Note that the elimination of double in the term F (double $(x)$ ) is not due to the outer function symbol F , but due to a collapsing argument filtering for double itself. For that reason a defined symbol like double may only be ignored if all its occurrences are in positions which are filtered away by the function symbols above them. Moreover, similar to the refinement of $\mathrm{CAP}_{v}$, we build usable rules only from those subterms of right-hand sides of dependency pairs that do not occur in the corresponding left-hand side of the dependency pair.

Definition 11 (Usable Rules w.r.t. Argument Filtering) Let $\pi$ be an argument filtering. For an n-ary symbol $f$, the set $\mathcal{R e g P o s}{ }_{\pi}(f)$ of regarded positions is $\{i\}$, if $\pi(f)=i$, and it is $\left\{i_{1}, \ldots, i_{m}\right\}$, if $\pi(f)=\left[i_{1}, \ldots, i_{m}\right]$. For a term, the usable rules w.r.t. $\pi$ are the smallest set of rules such that

- $\mathcal{U}(x, \pi)=\varnothing$ for $x \in \mathcal{V}$ and
- $\mathcal{U}\left(f\left(t_{1}, \ldots, t_{n}\right), \pi\right)=R l s(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r, \pi) \cup \bigcup_{j \in \operatorname{RegPos}_{\pi}(f)} \mathcal{U}\left(t_{j}, \pi\right)$.

For a term $s$ with $\mathcal{V}(t) \subseteq \mathcal{V}(s)$, we define $\mathcal{U}_{s}(t, \pi)=\varnothing$ if $t$ is a subterm of $s$. Otherwise, the definition is similar to $\mathcal{U}(t, \pi)$, i.e.,
$\mathcal{U}_{s}\left(f\left(t_{1}, \ldots, t_{n}\right), \pi\right)=R l s(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r, \pi) \cup \bigcup_{j \in \mathcal{R e g} \operatorname{Pos}_{\pi}(f)} \mathcal{U}_{s}\left(t_{j}, \pi\right)$.
Moreover, for any set $\mathcal{P}$ of dependency pairs, let $\mathcal{U}(\mathcal{P}, \pi)=\bigcup_{s \rightarrow t \in \mathcal{P}} \mathcal{U}_{s}(t, \pi)$.
To prove the soundness of our refinement for innermost termination proofs, we need the following lemma. For a reduction pair $(\succsim, \succ)$, the pair $\left(\succsim_{\pi}, \succ_{\pi}\right)$ results from applying an argument filtering, where $t \succsim_{\pi} u$ iff $\pi(t) \succsim \pi(u)$ and $t \succ_{\pi} u$ iff $\pi(t) \succ \pi(u)$. In [2] it was shown that $\left(\succsim_{\pi}, \succ_{\pi}\right)$ is indeed a reduction pair as well.

Lemma 12 (Properties of Usable Rules) Let $\mathcal{R}$ be a TRS, let $\pi$ be an argument filtering, let $(\succsim, \succ)$ be a reduction pair, and let $s$ and $t$ be terms with $\mathcal{V}(t) \subseteq \mathcal{V}(s)$, where $s$ is in normal form. Then we have
(i) $\mathcal{U}_{s \sigma}(t \sigma, \pi) \subseteq \mathcal{U}_{s}(t, \pi) \subseteq \mathcal{U}(t, \pi)$ for all substitutions $\sigma$
(ii) $t \rightarrow_{\mathcal{R}} u$ implies $\mathcal{U}_{s}(t, \pi) \supseteq \mathcal{U}_{s}(u, \pi)$
(iii) If $l \succsim_{\pi} r$ holds for all $l \rightarrow r \in \mathcal{U}_{s}(t, \pi)$ and $t \rightarrow_{\mathcal{R}} u$, then $t \succsim_{\pi} u$.
(iv) If $l \succsim_{\pi} r$ holds for all $l \rightarrow r \in \mathcal{U}_{s}(t, \pi)$ and $t \rightarrow_{\mathcal{R}}^{*} u$, then $t \succsim_{\gtrsim \pi} u$.

Proof.
(i) We use structural induction on $t$. If $t$ is a variable, then $t$ is a subterm of $s$ and thus, $\mathcal{U}_{s \sigma}(t \sigma, \pi)=\mathcal{U}_{s}(t, \pi)=\varnothing$. Otherwise, $t$ has the form $f\left(t_{1}, \ldots, t_{n}\right)$. Then

$$
\begin{aligned}
& \mathcal{U}_{s \sigma}(t \sigma, \pi)=R l s(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r, \pi) \cup \bigcup_{j \in \operatorname{RegPos}_{\pi}(f)} \mathcal{U}_{s \sigma}\left(t_{j} \sigma, \pi\right) \\
& \quad \stackrel{\text { (ind. })}{\subseteq} R l s(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r, \pi) \cup \bigcup_{j \in \operatorname{RegPos}}^{\pi}(f) \\
& \\
& \quad \mathcal{U}_{s}\left(t_{j}, \pi\right)=\mathcal{U}_{s}(t, \pi) \\
& \quad \subseteq R l s(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r, \pi) \cup \bigcup_{j \in \operatorname{RegPos}_{\pi}(f)} \mathcal{U}\left(t_{j}, \pi\right)=\mathcal{U}(t, \pi)
\end{aligned}
$$

(ii) Let $t \rightarrow_{\mathcal{R}} u$ using the rule $l \rightarrow r \in \mathcal{R}$. We perform structural induction on the position $p$ of the redex. If $p=\epsilon$ then $t=l \sigma \rightarrow_{\mathcal{R}} r \sigma=u$ for a substitution $\sigma$. As $t$ can be reduced, it is no normal form and thus, no subterm of $s$. Hence, $\mathcal{U}_{s}(t, \pi) \supseteq \mathcal{U}(r, \pi) \supseteq \mathcal{U}_{s}(r \sigma, \pi)=\mathcal{U}_{s}(u, \pi)$, by (i).
Otherwise $p=j p^{\prime}, t=f\left(t_{1} \ldots t_{j} \ldots t_{n}\right), u=f\left(t_{1} \ldots u_{j} \ldots t_{n}\right)$, and $t_{j} \rightarrow \mathcal{R} u_{j}$. If $j \notin \mathcal{R e g P o s} \pi(f)$, then $\mathcal{U}_{s}(t, \pi)=\mathcal{U}_{s}(u, \pi)$. If $j \in \mathcal{R} \operatorname{egPos} \pi(f)$, then

$$
\begin{aligned}
& \mathcal{U}_{s}(t, \pi)=R l s(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r, \pi) \cup \ldots \cup \mathcal{U}_{s}\left(t_{j}, \pi\right) \cup \ldots \\
& \quad(\text { ind. }) \\
& \quad \text { Rls }(f) \cup \bigcup_{l \rightarrow r \in R l s(f)} \mathcal{U}(r, \pi) \cup \ldots \cup \mathcal{U}_{s}\left(u_{j}, \pi\right) \cup \ldots=\mathcal{U}_{s}(u, \pi) .
\end{aligned}
$$

(iii) We use induction on the position $p$ of the redex. If $p=\epsilon$ then $t=l \sigma \rightarrow_{\mathcal{R}}$ $r \sigma=u$. Again, $t$ is not a normal form and therefore, no subterm of $s$. Hence, $l \rightarrow r \in \mathcal{U}_{s}(t, \pi)$, so $l \succsim_{\pi} r$ and $t \succsim_{\pi} u$, since $\succsim_{\pi}$ is stable.
If $p=j p^{\prime}$, we have $t=f\left(t_{1} \ldots t_{j} \ldots t_{n}\right), u=f\left(t_{1} \ldots u_{j} \ldots t_{n}\right)$, and $t_{j} \rightarrow \mathcal{R} u_{j}$. If $j \notin \mathcal{R e g P o s} \pi(f)$, then $\pi(t)=\pi(u)$ and thus, $t \succsim \pi u$. Otherwise, $j \in$ $\mathcal{R e g P o s}_{\pi}(f)$ and hence, $\mathcal{U}_{s}(t, \pi) \supseteq \mathcal{U}_{s}\left(t_{j}, \pi\right)$. So we can apply the induction hypothesis and conclude $t_{j} \succsim_{\pi} u_{j}$. Monotonicity of $\succsim_{\pi}$ implies $t \succsim_{\pi} u$.
(iv) This follows from (ii) and (iii) by induction on the number of reduction steps.

Now we can refine the innermost termination technique of Thm. 8 (c) and (d) to the following one where the set of usable rules is reduced significantly.

Theorem 13 (Improved Innermost Termination with DPs) $\mathcal{R}$ is innermost terminating if for any cycle $\mathcal{P}$ of the (estimated) innermost dependency graph, there is a reduction pair $(\succsim, \succ)$ and an argument filtering $\pi$ such that both
(c) $\pi(s) \succ \pi(t)$ for one dependency pair $s \rightarrow t$ from $\mathcal{P}$ and
$\pi(s) \succsim \pi(t)$ or $\pi(s) \succ \pi(t)$ for all other dependency pairs $s \rightarrow t$ from $\mathcal{P}$
(d) $\pi(l) \succsim \pi(r)$ for all $l \rightarrow r \in \mathcal{U}(\mathcal{P}, \pi)$

Proof. By Thm. 4, we have to show absence of infinite innermost chains. Let $s_{1} \rightarrow t_{1}, s_{2} \rightarrow t_{2}, \ldots$ be an infinite innermost chain from the cycle $\mathcal{P}$. So there is a substitution $\sigma$ with $t_{j} \sigma \xrightarrow{\text { i }} \mathcal{R}^{*} s_{j+1} \sigma$ for all $j$, where all $s_{j}$ and $s_{j} \sigma$ are in normal form. From (d) we get $l \succsim_{\pi} r$ for all $l \rightarrow r \in \mathcal{U}_{s_{j}}\left(t_{j}, \pi\right)$. Since $\mathcal{U}_{s_{j} \sigma}\left(t_{j} \sigma, \pi\right) \subseteq$ $\mathcal{U}_{s_{j}}\left(t_{j}, \pi\right)$ by Lemma 12 (i), we also have $l \succsim_{\pi} r$ for all $l \rightarrow r \in \mathcal{U}_{s_{j} \sigma}\left(t_{j} \sigma, \pi\right)$. Hence, we can use Lemma 12 (iv) to obtain $t_{j} \sigma \succsim_{\pi} s_{j+1} \sigma$. By (c) and closure of $\succ_{\pi}$ under substitutions, we obtain $s_{1} \sigma \succsim_{\pi} t_{1} \sigma \succsim_{\pi} s_{2} \sigma \succsim_{\pi} \ldots$ where $s_{j} \sigma \succ_{\pi} t_{j} \sigma$ holds for infinitely many $j$ in contradiction to the well-foundedness of $\succ_{\pi}$.

Example 14 This TRS of [18] for list reversal shows the advantages of Thm. 13.

$$
\begin{align*}
\operatorname{rev}(\operatorname{nil}) & \rightarrow \operatorname{nil}  \tag{16}\\
\operatorname{rev}(\operatorname{cons}(x, l)) & \rightarrow \operatorname{cons}(\operatorname{rev} 1(x, l), \operatorname{rev} 2(x, l))  \tag{17}\\
\operatorname{rev} 1(x, \operatorname{nil}) & \rightarrow x  \tag{18}\\
\operatorname{rev} 1(x, \operatorname{cons}(y, l)) & \rightarrow \operatorname{rev} 1(y, l)  \tag{19}\\
\operatorname{rev} 2(x, \operatorname{nil}) & \rightarrow \operatorname{nil}  \tag{20}\\
\operatorname{rev} 2(x, \operatorname{cons}(y, l)) & \rightarrow \operatorname{rev}(\operatorname{cons}(x, \operatorname{rev}(\operatorname{rev} 2(y, l)))) \tag{21}
\end{align*}
$$

When proving innermost termination with Thm. 8, for the cycle of the REVand REV2-dependency pairs, we would obtain inequalities from the dependency pairs and $\pi(l) \succsim \pi(r)$ for all rules $l \rightarrow r$, since all rules are usable. But with standard reduction pairs which are based on lexicographic or recursive path orders possibly with status (RPOS), Knuth-Bendix orders (KBO), or polynomial orders, these constraints are not satisfiable for any argument filtering.

To prove this for LPO, $\mathrm{RPO}(\mathrm{S})$, and KBO , we first show that if an argument position is eliminated by an argument filtering $\pi$, then the constraints cannot be satisfied. From (18) we obtain $1 \in \operatorname{RegPos}_{\pi}(\mathrm{rev} 1)$ which leads to $2 \in \mathcal{R e g P o s}_{\pi}(\mathrm{rev} 1)$ and $1,2 \in \operatorname{RegPos}_{\pi}($ cons $)$ by using (19) twice, so $\pi(\mathrm{rev} 1)=$ $\pi($ cons $)=[1,2]$. Using (17) we obtain $1 \in \mathcal{R e g P o s}{ }_{\pi}(\mathrm{rev})$. Now we can conclude $\pi(\mathrm{rev} 2)=[1,2]$ from (21). If we have $\pi(\mathrm{rev})=1$, then (17) yields a contradiction to the subterm property. Hence, $\pi(\mathrm{rev})=[1]$. Thus, if we search for a simplification order such that the rules are weakly decreasing, then we are not allowed to drop any argument or function symbol in the filtering. Hence, it is sufficient to examine whether the orders above are able to make the unfiltered rules weakly decreasing.

There is no KBO satisfying these constraints since (17) is duplicating. If we want to orient the constraints by some lexicographic or recursive path order, we need a precedence with rev2 $>$ rev due to (21). But this precedence cannot be extended further such that (17) can be oriented.

There is also no polynomial order such that the rules are weakly decreasing. A polynomial interpretation has the following form.

$$
\begin{array}{llll}
\mathcal{P o l}(\operatorname{rev}(l)) & =p_{1}(l), & \text { where } \quad p_{1}(l)=p_{1}^{\prime} \cdot l^{n_{1}}+p_{1}^{\prime \prime}(l) \\
\mathcal{P o l}(\operatorname{rev} 1(x, l)) & =p_{2}(x, l), & & \text { where } p_{2}(x, l)=p_{2}^{\prime}(x) \cdot l^{n_{2}}+p_{2}^{\prime \prime}(x, l) \\
\mathcal{P o l}(\operatorname{rev} 2(x, l)) & =p_{3}(x, l), & & \text { where } p_{3}(x, l)=p_{3}^{\prime}(x) \cdot l^{n_{3}}+p_{3}^{\prime \prime}(x, l) \\
\mathcal{P o l}(\operatorname{cons}(x, l)) & =p_{4}(x, l), & & \text { where } p_{4}(x, l)=p_{4}^{\prime}(x) \cdot l^{n_{4}}+p_{4}^{\prime \prime}(x, l) \\
\mathcal{P o l}(\text { nil }) & & =p_{5} &
\end{array}
$$

Here, $n_{1}, n_{2}, n_{3}, n_{4}$ denote the highest exponents used for $l$ in the respective polynomials, where $p_{i}^{\prime}$ and $p_{i}^{\prime \prime}$ are polynomials with coefficients from $\mathbb{N}$. So in $p_{1}^{\prime \prime}(l), p_{2}^{\prime \prime}(x, l), p_{3}^{\prime \prime}(x, l), p_{4}^{\prime \prime}(x, l)$, the variable $l$ occurs only with exponents smaller than the corresponding $n_{i}$. Similar to the argumentation above, where we showed that with simplification orders one may not filter away any arguments, it is easy to show that $\mathcal{P o l}(\operatorname{rev} 1(x, l)), \mathcal{P} o l(\operatorname{rev} 2(x, l))$, and $\mathcal{P o l}(\operatorname{cons}(x, l))$ must depend on $x$ and $l$ and $\mathcal{P o l}(\operatorname{rev}(l))$ must depend on $l$. Hence, all values $n_{i}$ must be at least 1 and the polynomials $p_{i}^{\prime}$ are not the number 0 .

From the constraints of (17) and (21) we obtain

$$
\begin{aligned}
\mathcal{P} o l(\operatorname{rev}(\operatorname{cons}(x, l))) & \geq \mathcal{P} o l(\operatorname{cons}(\operatorname{rev} 1(x, l), \operatorname{rev} 2(x, l))) \\
\mathcal{P} o l(\operatorname{rev} 2(x, \operatorname{cons}(x, l))) & \geq \mathcal{P} o l(\operatorname{rev}(\operatorname{cons}(x, \operatorname{rev}(\operatorname{rev} 2(x, l))))) .
\end{aligned}
$$

We now examine those parts of the polynomials which have the largest exponent for $l$. So for large enough instantiations of $l$ (and instantiations of $x$ where the $p_{i}^{\prime}$ are non-zero) we must have

$$
\begin{align*}
p_{1}^{\prime} \cdot p_{4}^{\prime}(x)^{n_{1}} \cdot l^{n_{1} \cdot n_{4}} & \geq p_{4}^{\prime}\left(p_{2}^{\prime}(x) \cdot l^{n_{2}}\right) \cdot p_{3}^{\prime}(x)^{n_{4}} \cdot l^{n_{3} \cdot n_{4}}  \tag{22}\\
p_{3}^{\prime}(x) \cdot p_{4}^{\prime}(x)^{n_{3}} \cdot l^{n_{3} \cdot n_{4}} & \geq p_{4}^{\prime}(x)^{n_{1}} \cdot p_{1}^{\prime n_{1} \cdot n_{4}+1} \cdot p_{3}^{\prime}(x)^{n_{1}^{2} \cdot n_{4}} \cdot l^{n_{1}^{2} \cdot n_{3} \cdot n_{4}} \tag{23}
\end{align*}
$$

Comparison of the highest exponents of $l$ yields $n_{1} \cdot n_{4} \geq n_{3} \cdot n_{4} \geq n_{1}^{2} \cdot n_{3} \cdot n_{4}$ and thus, $n_{1}=n_{3}=1$. Moreover, $p_{4}^{\prime}(x)$ may not depend on $x$, since otherwise
(22) would imply $n_{1} \cdot n_{4} \geq n_{3} \cdot n_{4}+n_{2}$. Now (22) and (23) simplify to

$$
\begin{align*}
p_{1}^{\prime} & \geq p_{3}^{\prime}(x)^{n_{4}}  \tag{24}\\
p_{3}^{\prime}(x) & \geq p_{1}^{\prime n_{4}+1} \cdot p_{3}^{\prime}(x)^{n_{4}} \tag{25}
\end{align*}
$$

From (24) and (25) we can conclude that $p_{3}^{\prime}(x)$ does not depend on $x$ and $p_{3}^{\prime}=$ $p_{1}^{\prime}=1$. Hence, our polynomial interpretation is as follows:

$$
\begin{array}{ll}
\mathcal{P o l}(\operatorname{rev}(l)) & =l+p_{1}^{\prime \prime} \\
\operatorname{Pol}(\operatorname{rev} 1(x, l)) & =p_{2}^{\prime}(x) \cdot l^{n_{2}}+p_{2}^{\prime \prime}(x, l) \\
\operatorname{Pol}(\operatorname{rev} 2(x, l)) & =l+p_{3}^{\prime \prime}(x) \\
\operatorname{Pol}(\operatorname{cons}(x, l)) & =p_{4}^{\prime} \cdot l^{n_{4}}+p_{4}^{\prime \prime}(x, l) \\
\operatorname{Pol}(\text { nil }) & =p_{5}
\end{array}
$$

Now we obtain

$$
\begin{align*}
p_{4}^{\prime} \cdot p_{5}^{n_{4}}+p_{4}^{\prime \prime}\left(x, p_{5}\right)+p_{1}^{\prime \prime} & =  \tag{26}\\
\mathcal{P o l}(\operatorname{rev}(\operatorname{cons}(x, \text { nil }))) & \geq  \tag{27}\\
\mathcal{P o l}(\operatorname{cons}(\operatorname{rev} 1(x, \operatorname{nil}), \operatorname{rev} 2(x, \text { nil }))) & \geq  \tag{28}\\
\mathcal{P o l}(\operatorname{cons}(x, \operatorname{rev} 2(x, \text { nil }))) & =  \tag{29}\\
p_{4}^{\prime} \cdot\left(p_{5}+p_{3}^{\prime \prime}(x)\right)^{n_{4}}+p_{4}^{\prime \prime}\left(x, p_{5}+p_{3}^{\prime \prime}(x)\right) & \geq  \tag{30}\\
p_{4}^{\prime} \cdot p_{5}^{n_{4}}+p_{4}^{\prime \prime}\left(x, p_{5}\right)+p_{4}^{\prime} \cdot p_{3}^{\prime \prime}(x)^{n_{4}} & \tag{31}
\end{align*}
$$

The step from (27) to (28) is due to the weak decreasingness of Rule (17) and the step from (28) to (29) follows from monotonicity and Rule (18). Note that these inequalities give a contradiction if one instantiates $x$ with a large enough value like $p_{1}^{\prime \prime}+1$, since $\mathcal{P o l}(\operatorname{rev} 2(x, l))$ and hence $p_{3}^{\prime \prime}(x)$ must depend on $x$.

So the most common orders that are amenable to automation fail when trying to prove termination according to Thm. 8. In contrast, when using Thm. 13 and a filtering with $\pi$ (cons) $=[2], \pi(\mathrm{REV})=\pi(\mathrm{rev})=1$, and $\pi(\mathrm{REV} 2)=\pi(\mathrm{rev} 2)=2$, we do not obtain any constraints from the rev1-rules and all filtered constraints can be oriented by the embedding order.

Our experiments with the system AProVE show that Thm. 9 and 13 indeed improve upon Thm. 8 in practice by increasing power (in particular if reduction pairs are based on simple fast orders like the embedding order) and by reducing runtimes (in particular if reduction pairs are based on more complex orders). More details are given in the appendix.

## 5 Transforming Dependency Pairs

To increase the power of the dependency pair technique, a dependency pair may be transformed into several new pairs by narrowing, rewriting, and instantiation $[2,12]$. A term $t^{\prime}$ is an $\mathcal{R}$-narrowing of $t$ with the $m g u$, if a non-variable subterm $\left.t\right|_{p}$ of $t$ unifies with the left-hand side of a (variable-renamed) rule $l \rightarrow r \in \mathcal{R}$ with mgu $\mu$, and $t^{\prime}=t[r]_{p} \mu$. To distinguish the variants for termination and innermost termination, we speak of $t$ - and $i$-narrowing resp. -instantiation.

Definition 15 (Transformations) For a TRS $\mathcal{R}$ and a set $\mathcal{P}$ of pairs of terms

- $\mathcal{P} \uplus\{s \rightarrow t\}$ t-narrows to $\mathcal{P} \uplus\left\{s \mu_{1} \rightarrow t_{1}, \ldots, s \mu_{n} \rightarrow t_{n}\right\}$ iff $t_{1}, \ldots, t_{n}$ are all $\mathcal{R}$-narrowings of $t$ with the mgu's $\mu_{1}, \ldots, \mu_{n}$ and $t$ does not unify with (variable-renamed) left-hand sides of pairs in $\mathcal{P}$. Moreover, $t$ must be linear.
- $\mathcal{P} \uplus\{s \rightarrow t\}$ i-narrows to $\mathcal{P} \uplus\left\{s \mu_{1} \rightarrow t_{1}, \ldots, s \mu_{n} \rightarrow t_{n}\right\}$ iff $t_{1}, \ldots, t_{n}$ are all $\mathcal{R}$-narrowings of $t$ with the mgu's $\mu_{1}, \ldots, \mu_{n}$ such that $s \mu_{i}$ is in normal form. Moreover, for all $v \rightarrow w \in \mathcal{P}$ where $t$ unifies with the (variable-renamed) left-hand side $v$ by a mgu $\mu$, one of the terms $s \mu$ or $v \mu$ must not be in normal form.
- $\mathcal{P} \uplus\{s \rightarrow t\}$ rewrites to $\mathcal{P} \uplus\left\{s \rightarrow t^{\prime}\right\}$ iff $\mathcal{U}\left(\left.t\right|_{p}\right)$ is non-overlapping and $t \rightarrow_{\mathcal{R}} t^{\prime}$, where $p$ is the position of the redex.
- $\mathcal{P} \uplus\{s \rightarrow t\}$ is t-instantiated to $\mathcal{P} \uplus\{s \mu \rightarrow t \mu \mid \mu=m g u(\operatorname{REN}(\operatorname{CAP}(w)), s), v \rightarrow w \in \mathcal{P}\}$.
- $\mathcal{P} \uplus\{s \rightarrow t\}$ is i-instantiated to $\mathcal{P} \uplus\left\{s \mu \rightarrow t \mu \mid \mu=m g u\left(\operatorname{CAP}_{v}(w), s\right), v \rightarrow w \in \mathcal{P}, s \mu, v \mu\right.$ are normal forms $\}$.

For innermost termination, Def. 15 extends the transformations of $[2,12]$ by permitting their application for a larger set of TRSs. In [12], narrowing a pair $s \rightarrow t$ was not permitted if $t$ unifies with the left-hand side of some dependency pair, whereas now this is possible under certain conditions. Rewriting dependency pairs was only allowed if all usable rules for the current cycle were non-overlapping, whereas now this is only required for the usable rules of the redex to be rewritten. Finally, when instantiating dependency pairs, in contrast to [12] one can now use $\mathrm{CAP}_{v}$. Moreover, for both instantiation and narrowing of dependency pairs, now one only has to consider instantiations which turn left-hand sides of dependency pairs into normal forms.

The following theorem states that in the techniques for termination and innermost termination proofs (Thm. 9 and 13), instead of the original dependency pairs one may regard pairs that are transformed according to Def. 15. Of course, then Thm. 9 and 13 have to be updated accordingly (e.g., in Thm. 9, instead of $\mathcal{P} \subseteq D P\left(\mathcal{R}_{i}\right)$ we now permit that $\mathcal{P}$ results from dependency pairs of $D P\left(\mathcal{R}_{i}\right)$ by transformations).

Theorem 16 (Narrowing, Rewriting, Instantiation) Let $D P(\mathcal{R})^{\prime}$ result from $D P(\mathcal{R})$ by $t$-narrowing and t-instantiation (for termination) resp. by $i$ narrowing, rewriting, and i-instantiation (for innermost termination). If the dependency pair constraints for (innermost) termination are satisfiable using $D P(\mathcal{R})^{\prime}$, then $\mathcal{R}$ is (innermost) terminating. Moreover, if certain reduction pairs and argument filterings satisfy the constraints for $D P(\mathcal{R})$, then the same reduction pairs and argument filterings satisfy the constraints for $\operatorname{DP}(\mathcal{R})^{\prime} .{ }^{3}$

[^2]Proof. For soundness of the transformations, we prove that if there is an infinite (innermost) chain of pairs from $D P(\mathcal{R})$, then there is also an infinite (innermost) chain of pairs from $D P(\mathcal{R})^{\prime} .{ }^{4}$ Hence, if the dependency pair constraints using $D P(\mathcal{R})^{\prime}$ are satisfiable, then by the soundness of the dependency pair approach, the TRS is (innermost) terminating. For completeness, we show that if the dependency pair constraints for $\operatorname{DP}(\mathcal{R})$ using the estimated (innermost) dependency graph of Def. 5 are satisfied by some reduction pairs and argument filterings, then the same reduction pairs and argument filterings satisfy the constraints for $D P(\mathcal{R})^{\prime}$.

- narrowing: Soundness of t-narrowing is proved in [2, Thm. 27] and soundness of i-narrowing is proved in [12, Thm. 12] (the soundness of the refined version of i-narrowing in Def. 15 follows from the fact that in innermost chains, one regards a substitution such that the instantiated left components of all dependency pair are in normal form).
For completeness of t-narrowing, we assume that $D P(\mathcal{R})^{\prime}$ is the result of t-narrowing a dependency pair $s \rightarrow t$ from $D P(\mathcal{R})$. In this transformation, $s \rightarrow t$ was replaced by its narrowings $s \mu_{1} \rightarrow t_{1}, \ldots, s \mu_{n} \rightarrow t_{n}$.
We first show that if $\mathcal{P}^{\prime}$ is a cycle of the estimated dependency graph of $D P(\mathcal{R})^{\prime}$ containing some pair $s \mu_{i} \rightarrow t_{i}$, then $\mathcal{P}=\mathcal{P}^{\prime} \backslash\left\{s \mu_{1} \rightarrow t_{1}, \ldots, s \mu_{n} \rightarrow\right.$ $\left.t_{n}\right\} \cup\{s \rightarrow t\}$ is a cycle in the estimated dependency graph of $D P(\mathcal{R})$. Assume there is an arc from $v \rightarrow w$ to $s \mu_{i} \rightarrow t_{i}$ in the estimated dependency graph of $D P(\mathcal{R})^{\prime}$, i.e., $\operatorname{REN}(\operatorname{CAP}(w)) \sigma=s \mu_{i} \sigma$ for some substitution $\sigma$. Then there is also an arc from $v \rightarrow w$ to $s \rightarrow t$ in the estimated dependency graph of $D P(\mathcal{R})$ using the same substitution $\sigma$ on the variables of $v \rightarrow w$ by extending it to behave like $\mu_{i} \sigma$ on the variables of $s$ and $t$. (Recall that we may assume that the variables in $s \rightarrow t$ are disjoint from all other variables.) Similarly, if there is an arc from $s \mu_{i} \rightarrow t_{i}$ to $v \rightarrow w$ (i.e., $\operatorname{REN}\left(\operatorname{CAP}\left(t_{i}\right)\right) \sigma=v \sigma$ ), then there is also an arc from $s \rightarrow t$ to $v \rightarrow w$ in the estimated dependency graph of $D P(\mathcal{R})$ using a similar substitution $\sigma$ as above. The reason is that $t \mu_{i} \rightarrow_{\mathcal{R}} t_{i}$, and hence, $\operatorname{REN}\left(\operatorname{CAP}\left(t_{i}\right)\right)$ is an instance of $\operatorname{REN}\left(\operatorname{CAP}\left(t \mu_{i}\right)\right)$ which in turn is an instance of $\operatorname{REN}(\operatorname{CAP}(t))$. Thus, by extending $\sigma$ to the variables in $\operatorname{REN}(\operatorname{CAP}(t))$ in an appropriate way, we also obtain $\operatorname{REN}(\operatorname{CAP}(t)) \sigma=v \sigma$.
Now we show that if a reduction pair $(\succsim, \succ)$ and an argument filtering $\pi$ satisfy all constraints for a cycle $\mathcal{P}=\mathcal{P}^{\prime} \backslash\left\{s \mu_{1} \rightarrow t_{1}, \ldots, s \mu_{n} \rightarrow t_{n}\right\} \cup\{s \rightarrow t\}$, then they also satisfy the constraints for the cycle $\mathcal{P}^{\prime}$. These constraints only differ in that $s \succsim_{\pi} t$ resp. $s \succ_{\pi} t$ is replaced by $s \mu_{i} \succsim_{\pi} t_{i}$ resp. $s \mu_{i} \succ_{\pi} t_{i}$. The constraints of Type (b) are the same. Note that if $\mathcal{P}$ and $\mathcal{P}^{\prime}$ contain a pair $F(\ldots) \rightarrow \ldots$, then for every function symbol $g$ occurring below the root of right-hand sides in pairs of $\mathcal{P}$ or $\mathcal{P}^{\prime}$, we have $g \leq_{d} f$. Then $s \succsim_{\pi} t$ implies $s \mu_{i} \succsim_{\pi} t \mu_{i} \succsim_{\pi} t_{i}$ by stability of $\succsim_{\pi}$ and by the fact that $t \mu_{i}$ rewrites to $t_{i}$
${ }^{4}$ The converse direction (i.e., if there is an infinite (innermost) chain of pairs from $D P(\mathcal{R})^{\prime}$ then there is also an infinite (innermost) chain of pairs from $D P(\mathcal{R})$ ) holds as well for rewriting, instantiation, and t-narrowing. For i-narrowing, this direction only holds if the usable rules are non-overlapping (cf. [2, Ex. 43] and [12, Thm. 17]).
using a $g$-rule for a function symbol $g \leq_{d} f$. Hence, the constraints of Type (b) imply that all $g$-rules are weakly decreasing. Similarly, $s \succ_{\pi} t$ implies $s \mu_{i} \succ_{\pi} t \mu_{i} \succsim_{\pi} t_{i}$.
Now we prove completeness of i-narrowing. As for $t$-narrowing, we first show that if $\mathcal{P}^{\prime}$ is a cycle of the estimated innermost dependency graph of $D P(\mathcal{R})^{\prime}$ containing some pair $s \mu_{i} \rightarrow t_{i}$, then $\mathcal{P}=\mathcal{P}^{\prime} \backslash\left\{s \mu_{1} \rightarrow t_{1}, \ldots, s \mu_{n} \rightarrow t_{n}\right\} \cup\{s \rightarrow$ $t\}$ is a cycle in the estimated innermost dependency graph of $D P(\mathcal{R})$. As in the termination case, one can show that arcs from $v \rightarrow w$ to $s \mu_{i} \rightarrow$ $t_{i}$ correspond to arcs from $v \rightarrow w$ to $s \rightarrow t$ in the estimated innermost dependency graph of $\operatorname{DP}(\mathcal{R})$. Similarly, if there is an arc from $s \mu_{i} \rightarrow t_{i}$ to $v \rightarrow w$ (i.e., $\left.\mathrm{CAP}_{s \mu_{i}}\left(t_{i}\right) \sigma=v \sigma\right)$, then there is also an arc from $s \rightarrow t$ to $v \rightarrow w$ in the estimated dependency graph of $D P(\mathcal{R})$ using a similar substitution $\sigma$. The reason is again that $\operatorname{CAP}_{s \mu_{i}}\left(t_{i}\right)$ is an instance of $\operatorname{CAP}_{s \mu_{i}}\left(t \mu_{i}\right)$ which in turn is an instance of $\operatorname{CAP}_{s}(t)$. To see this, recall that $t \mu_{i}$ rewrites to $t_{i}$. Thus, the subterm of $t \mu_{i}$ that is the redex in this reduction cannot occur in $s \mu_{i}$, since $s \mu_{i}$ must be a normal form. Hence, in $\mathrm{CAP}_{s \mu_{i}}\left(t \mu_{i}\right)$, this subterm (or a subterm containing this redex) is replaced by a fresh variable and thus, $\mathrm{CAP}_{s \mu_{i}}\left(t_{i}\right)$ is an instance of $\mathrm{CAP}_{s \mu_{i}}\left(t \mu_{i}\right)$. If a subterm of $t$ occurs also in $s$, then the corresponding subterm of $t \mu_{i}$ also occurs in $s \mu_{i}$. In contrast, there may subterms of $t \mu_{i}$ that occur in $s \mu_{i}$, whereas no corresponding subterm of $t$ occurs in $s$. This indicates that $\operatorname{CAP}_{s \mu_{i}}\left(t \mu_{i}\right)$ is an instance of $\operatorname{CAP}_{s}(t)$.
Next we show that if a reduction pair $(\succsim, \succ)$ and an argument filtering $\pi$ satisfy all constraints for a cycle $\mathcal{P}=\mathcal{P}^{\prime} \backslash\left\{s \mu_{1} \rightarrow t_{1}, \ldots, s \mu_{n} \rightarrow t_{n}\right\} \cup\{s \rightarrow t\}$, then they also satisfy the constraints for the cycle $\mathcal{P}^{\prime}$. One difference between these constraints is that $s \succsim_{\pi} t$ resp. $s \succ_{\pi} t$ is replaced by $s \mu_{i} \succsim_{\pi} t_{i}$ resp. $s \mu_{i} \succ_{\pi} t_{i}$. Note that $s \succsim_{\pi} t$ again implies $s \mu_{i} \succsim_{\pi} t \mu_{i} \succsim_{\pi} t_{i}$ by stability of $\succsim \pi$ and by the fact that $t \mu_{i}$ rewrites to $t_{i}$. Here, $t \mu_{i} \succsim t_{i}$ follows by Lemma 12 (iii), since all rules in $\mathcal{U}_{s \mu_{i}}\left(t \mu_{i}, \pi\right) \subseteq \mathcal{U}_{s}(t, \pi)$ are weakly decreasing (cf. Lemma 12 (i)). Similarly, $s \succ_{\pi} t$ implies $s \mu_{i} \succ_{\pi} t_{i}$.
The other difference is in the set of usable rules. But we have $\mathcal{U}_{s \mu_{i}}\left(t_{i}, \pi\right) \subseteq$ $\mathcal{U}_{s \mu_{i}}\left(t \mu_{i}, \pi\right) \subseteq \mathcal{U}_{s}(t, \pi)$ by Lemma 12 (ii) and (i). Therefore, we obtain $\mathcal{U}\left(\mathcal{P}^{\prime}, \pi\right)$ $\subseteq \mathcal{U}(\mathcal{P}, \pi)$.
- rewriting: We assume that $D P(\mathcal{R})^{\prime}$ is the result of rewriting a dependency pair $s \rightarrow t$ from $D P(\mathcal{R})$ to $s \rightarrow t^{\prime}$ (i.e., $t$ rewrites to $t^{\prime}$ at some position $p$ ). For soundness of our refined version of rewriting we adapt the proof of $[12$, Thm. 18]. Let $\ldots, s \rightarrow t, v \rightarrow w, \ldots$ be an innermost chain of pairs from $D P(\mathcal{R})$. Hence, there exists a substitution $\sigma$ with $t \sigma \stackrel{i}{\mathcal{R}}_{\mathcal{R}}^{*} v \sigma$ and $s \sigma, v \sigma$ are normal forms. Thus, $t \sigma$ is weakly innermost terminating. Due to the innermost reduction strategy, we can split up the reduction of $t \sigma$ into two parts. First, we reduce only on positions on or below $p$ until $\left.t\right|_{p} \sigma$ is a normal form $u$. Afterwards we perform the remaining reduction steps from $t \sigma[u]_{p}$ to $v \sigma$. The only rules applicable to $\left.t\right|_{p} \sigma$ are $\mathcal{U}\left(\left.t\right|_{p} \sigma\right)$ and as $\mathcal{U}\left(\left.t\right|_{p} \sigma\right)$ is non-overlapping, by $\left[15\right.$, Thm. 3.2.11 (1a) and (4a)], $\left.t\right|_{p} \sigma$ is confluent and terminating. With
$\left.\left.t\right|_{p} \rightarrow_{\mathcal{R}} t^{\prime}\right|_{p}$ we obtain $\left.\left.t\right|_{p} \sigma \rightarrow_{\mathcal{R}} t^{\prime}\right|_{p} \sigma$. Hence, $\left.t^{\prime}\right|_{p} \sigma$ is terminating as well and thus, it also reduces innermost to the same normal form $u$ using the confluence of $\left.t\right|_{p} \sigma$. So we have $t^{\prime} \sigma=t \sigma\left[\left.t^{\prime}\right|_{p} \sigma\right]_{p} \xrightarrow{\mathbf{i}} \stackrel{*}{\mathcal{R}} t \sigma[u]_{p}$. Afterwards, we can apply the same remaining steps as above that lead from $t \sigma[u]_{p}$ to $v \sigma$. Therefore $\ldots, s \rightarrow t^{\prime}, v \rightarrow w, \ldots$ is an innermost chain as well. The proof for the completeness of rewriting is analogous to the proof of completeness of i-narrowing.
- instantiation: Soundness of instantiation is proved in [12, Thm. 20] (the soundness of our refined version of i-instantiation is again due to the fact that in innermost chains one only regards substitutions which instantiate all lefthand sides of dependency pairs to normal forms). The completeness proofs are analogous to the completeness proofs for t-narrowing and i-narrowing, respectively.

By Thm. 16, these transformations never complicate (innermost) termination proofs (but they may increase the number of constraints by producing similar constraints that can be solved by the same argument filterings and reduction pairs). So sometimes the runtime is increased by these transformations. On the other hand, the transformations are often crucial for the success of the proof.

Example 17 In the following TRS [3], the minus-rules of Ex. 1 are extended with

$$
\begin{aligned}
\mathrm{le}(0, y) & \rightarrow \text { true } \\
\mathrm{le}(\mathrm{~s}(x), 0) & \rightarrow \text { false } \\
\mathrm{le}(\mathrm{~s}(x), \mathrm{s}(y)) & \rightarrow \mathrm{le}(x, y) \\
\text { quot }(x, \mathrm{~s}(y)) & \rightarrow \mathrm{if}(\operatorname{le}(\mathrm{~s}(y), x), x, \mathrm{~s}(y)) \\
\text { if }(\text { true }, x, y) & \rightarrow \mathrm{s}(\text { quot }(\operatorname{minus}(x, y), y)) \\
\text { if }(\text { false }, x, y) & \rightarrow 0
\end{aligned}
$$

When trying to prove innermost termination, no simplification order satisfies the constraints of Thm. 13 for the following cycle.

$$
\begin{align*}
\operatorname{QUOT}(x, \mathrm{~s}(y)) & \rightarrow \mathrm{IF}(\operatorname{le}(\mathrm{~s}(y), x), x, \mathrm{~s}(y))  \tag{32}\\
\mathrm{IF}(\text { true }, x, y) & \rightarrow \operatorname{QUOT}(\operatorname{minus}(x, y), y) \tag{33}
\end{align*}
$$

The reason is that from the dependency pair constraints of this cycle we obtain

$$
\begin{array}{r}
\pi(\mathrm{IF}(\operatorname{true}, x, \mathrm{~s}(y))) \\
\succsim \\
\pi(\mathrm{QUOT}(\operatorname{minus}(x, \mathrm{~s}(y)), \mathrm{s}(y))) \\
\pi(\mathrm{IF}(\mathrm{le}(\mathrm{~s}(y), \operatorname{minus}(x, \mathrm{~s}(y))), \operatorname{minus}(x, \mathrm{~s}(y)), \mathrm{s}(y)))
\end{array}
$$

where one of the constraints has to be strict. Hence, we have

$$
\pi(\mathrm{IF}(\operatorname{true}, x, \mathrm{~s}(y))) \succ \pi(\mathrm{IF}(\mathrm{le}(\mathrm{~s}(y), \operatorname{minus}(x, \mathrm{~s}(y))), \operatorname{minus}(x, \mathrm{~s}(y)), \mathrm{s}(y)))
$$

From the minus-rules we see that an argument filtering $\pi$ must not drop the first argument of minus. Hence, by the subterm property we get $\pi(\operatorname{minus}(x, y)) \succsim \pi(x)$. This leads to

$$
\begin{equation*}
\pi(\mathrm{IF}(\operatorname{true}, x, \mathrm{~s}(y))) \succ \pi(\mathrm{IF}(\mathrm{le}(\mathrm{~s}(y), x), x, \mathrm{~s}(y))) . \tag{34}
\end{equation*}
$$

In order to obtain a contradiction we first show the following property.

$$
\begin{equation*}
\pi(\text { le }(\mathrm{s}(\text { true }), \mathrm{s}(\text { true }))) \succsim \pi(\text { true }) \tag{35}
\end{equation*}
$$

If $\pi(\mathrm{le})=[]$, then using the first le-rule we can directly conclude that (35) holds. Otherwise, by the last le-rule we get $\pi(\mathrm{le}(\mathrm{s}($ true $), \mathrm{s}($ true $))) \succsim \pi(\mathrm{le}($ true, true $))$ and $\pi($ le(true, true $)) \succsim \pi$ (true) by the subterm property.

Now, using (34), (35), and the substitution $\{x / \mathrm{s}$ (true), $y /$ true $\}$ we obtain the desired contradiction.

$$
\begin{array}{r}
\pi(\mathrm{IF}(\text { true }, \mathrm{s}(\text { true }), \mathrm{s}(\text { true }))) \\
\pi(\mathrm{IF}(\mathrm{le}(\mathrm{~s}(\text { true }), \mathrm{s}(\text { true })), \mathrm{s}(\text { true }), \mathrm{s}(\text { true }))) \\
\pi(\mathrm{IF}(\text { true }, \mathrm{s}(\text { true }), \mathrm{s}(\text { true }))) .
\end{array}
$$

On the other hand, when transforming the dependency pairs, the resulting constraints can easily be satisfied by simplification orders. Intuitively, $x \succ$ minus $(x, y)$ only has to be satisfied if $\operatorname{le}(\mathrm{s}(y), x)$ reduces to true. This argumentation can be simulated using the transformations of Def. 15. By i-narrowing, we perform a case analysis on how the le-term in (32) can be evaluated. In the first narrowing, $x$ is instantiated by 0 . This results in a pair $\operatorname{QUOT}(0, \mathrm{~s}(y)) \rightarrow$ IF (false, $0, \mathrm{~s}(y))$ which is not in a cycle. The other narrowing is

$$
\begin{equation*}
\operatorname{QUOT}(\mathrm{s}(x), \mathrm{s}(y)) \rightarrow \mathrm{IF}(\mathrm{le}(y, x), \mathrm{s}(x), \mathrm{s}(y)) \tag{36}
\end{equation*}
$$

which forms a new cycle with (33). Now we perform i-instantiation of (33) and see that $x$ and $y$ must be of the form $\mathbf{s}(\ldots)$. So (33) is replaced by the new pair

$$
\begin{equation*}
\mathrm{IF}(\operatorname{true}, \mathrm{~s}(x), \mathrm{s}(y)) \rightarrow \mathrm{QUOT}(\operatorname{minus}(\mathrm{~s}(x), \mathrm{s}(y)), \mathrm{s}(y)) \tag{37}
\end{equation*}
$$

that forms a cycle with (36). Finally, we do a rewrite step on (37) and obtain

$$
\begin{equation*}
\mathrm{IF}(\operatorname{true}, \mathrm{~s}(x), \mathrm{s}(y)) \rightarrow \mathrm{QUOT}(\operatorname{minus}(x, y), \mathrm{s}(y)) \tag{38}
\end{equation*}
$$

The constraints from the resulting cycle $\{(36),(38)\}$ (and from all other cycles) can be solved by $\pi$ (minus) $=\pi($ QUOT $)=1, \pi(\mathrm{IF})=2$, and the embedding order.

The crucial problem with the refinement of Def. 15 is that these transformations may be applied infinitely many times. Therefore, we have developed restricted safe transformations which are guaranteed to terminate. Our experiments on the collections of examples from [3, 9,27$]$ show that whenever the proof
succeeds using narrowing, rewriting, and instantiation, then applying these safe transformations is sufficient.

A narrowing or instantiation step is safe if it reduces the number of pairs in cycles of the estimated (innermost) dependency graph. For a set of pairs $\mathcal{P}$, $\operatorname{SCC}(\mathcal{P})$ denotes the set of maximal cycles built from pairs of $\mathcal{P}$. Then, the transformation is safe if $\Sigma_{\mathcal{S} \in \mathrm{SCC}(\mathcal{P})}|\mathcal{S}|$ decreases. Moreover, it is also considered safe if by the transformation step, all descendants of some original dependency pair disappear from cycles. For every pair $s \rightarrow t, o(s \rightarrow t)$ denotes the original dependency pair whose repeated transformation led to $s \rightarrow t$. Now a transformation is also safe if $\left\{o(s \rightarrow t) \mid s \rightarrow t \in \bigcup_{\mathcal{S} \in \mathrm{SCC}(\mathcal{P})} \mathcal{S}\right\}$ decreases.

As an example, consider $\mathcal{R}=\{\mathrm{f}(\mathrm{a}) \rightarrow \mathrm{g}(\mathrm{b}), \mathrm{g}(x) \rightarrow \mathrm{f}(x)\}$. The estimated dependency graph has the cycle $\{\mathrm{F}(\mathrm{a}) \rightarrow \mathrm{G}(\mathrm{b}), \mathrm{G}(x) \rightarrow \mathrm{F}(x)\}$. Instantiation transforms the second pair into $G(b) \rightarrow F(b)$. Now there is no cycle anymore, since $\mathcal{F}(b)$ does not unify with $\mathcal{F}(a)$. Thus, this instantiation step is safe. Finally for each pair, one single narrowing and instantiation step which does not satisfy the above requirements is also considered safe. Hence, the narrowing and instantiation steps in Ex. 17 were safe as well.

As for termination, in innermost termination proofs we also benefit from considering the recursion hierarchy. So if $\mathcal{R}_{1}, \ldots, \mathcal{R}_{n}$ is a separation of the TRS $\mathcal{R}$ and $\mathcal{R}_{i}>_{d} \mathcal{R}_{j}$, then we show absence of innermost $\mathcal{R}$-chains built from $D P\left(\mathcal{R}_{j}\right)$ before dealing with $D P\left(\mathcal{R}_{i}\right)$. Now innermost rewriting a dependency pair $F(\ldots) \rightarrow \ldots$ is safe if it is performed with rules that do not depend on $f$ (i.e., with $g$-rules where $g<_{d} f$ ). The reason is that innermost termination of $g$ is already verified when proving innermost termination of $f$. So in Ex. 17, when proving innermost termination of the QUOT-cycle, we may assume innermost termination of minus and thus, the rewrite step from (37) to (38) was safe.

Definition 18 (Safe Transformations) Let $\mathcal{Q}$ result from a set $\mathcal{P}$ of pairs of terms by transforming $s \rightarrow t \in \mathcal{P}$ as in Def. 15. The transformation is safe if
(1) $s \rightarrow t$ was transformed by narrowing or instantiation and

- $\Sigma_{\mathcal{S} \in \mathrm{SCC}(\mathcal{P})}|\mathcal{S}|>\Sigma_{\mathcal{S} \in \operatorname{SCC}(\mathcal{Q})}|\mathcal{S}|$, or
- $\left\{o(s \rightarrow t) \mid s \rightarrow t \in \bigcup_{\mathcal{S} \in \operatorname{SCC}(\mathcal{P})} \mathcal{S}\right\} \supsetneq\left\{o(s \rightarrow t) \mid s \rightarrow t \in \bigcup_{\mathcal{S} \in \operatorname{SCC}(\mathcal{Q})} \mathcal{S}\right\}$
(2) $s \rightarrow t$ was transformed by innermost rewriting with the rule $l \rightarrow r$ and $\operatorname{root}(l)<_{d} f$ where $f^{\sharp}=\operatorname{root}(s)$
(3) $s \rightarrow t$ was transformed by narrowing and all previous steps which transformed $o(s \rightarrow t)$ to $s \rightarrow t$ were not narrowing steps
(4) $s \rightarrow t$ was transformed by instantiation and all previous steps which transformed $o(s \rightarrow t)$ to $s \rightarrow t$ were not instantiation steps

The following theorem proves that the repeated application of safe transformations is indeed terminating.

Theorem 19 (Termination) Let $\mathcal{R}$ have the separation $\mathcal{R}_{1}, \ldots, \mathcal{R}_{n}$ and $\mathcal{P} \subseteq$ $D P\left(\mathcal{R}_{i}\right)$. If there are no infinite innermost $\mathcal{R}$-chains from $D P\left(\mathcal{R}_{j}\right)$ for all $\mathcal{R}_{j}$ $<_{d} \mathcal{R}_{i}$, then any repeated application of safe transformations on $\mathcal{P}$ terminates.

Proof. We define a measure on sets of pairs $\mathcal{P}$ consisting of four components:
(a) $\left|\left\{o(s \rightarrow t) \mid s \rightarrow t \in \bigcup_{\mathcal{S} \in \operatorname{SCC}(\mathcal{P})} \mathcal{S}\right\}\right|$
(c) $|\mathcal{P}|$
(b) $\Sigma_{\mathcal{S} \in \operatorname{SCC}(\mathcal{P})}|\mathcal{S}|$
(d) $\mathcal{P}$

These 4-tuples are compared lexicographically by the usual order on naturals for components (a)-(c). For (d), we use the (multi)set extension of the innermost rewrite relation of $\bigcup_{\mathcal{R}_{j}<{ }_{d} \mathcal{R}_{i}} \mathcal{R}_{j}$. Thus, we obtain a well-founded relation $\succ$ where $\mathcal{P}_{1} \succ \mathcal{P}_{2}$ iff $\mathcal{P}_{1}$ 's measure is greater than the measure of $\mathcal{P}_{2}$. Due to (a), (b), and (d), any safe transformation of $\mathcal{P}$ with steps (1) or (2) decreases the measure of $\mathcal{P}$.

For a set of pairs $\mathcal{P}$, let $w(\mathcal{P})=\left\langle\mathcal{P}_{\neg n, \neg i}, \mathcal{P}_{n, \neg i}, \mathcal{P}_{\neg n, i}, \mathcal{P}_{n, i}\right\rangle . \mathcal{P}_{\neg n, \neg i}$ consists of those $s \rightarrow t \in \mathcal{P}$ where no (n)arrowing or (i)nstantiation was used to transform $o(s \rightarrow t)$ to $s \rightarrow t$. $\mathcal{P}_{n, \neg i}$ are the pairs where narrowing, but no instantiation was used, etc. Every safe transformation step decreases $w(\mathcal{P})$ lexicographically w.r.t. $\succ$ : Transformations with (1) or (2) decrease one component of $w(\mathcal{P})$ w.r.t. $\succ$ and do not modify the others. Transformations with (3) or (4) reduce the size of one component of $w(\mathcal{P})$ (so the component decreases w.r.t. $\succ$ according to (c)) and increase the size of some component on its right-hand side.

After each transformation, the current cycle or SCC of the estimated (innermost) dependency graph is re-computed. For this re-computation, one only has to regard the former neighbors of the transformed pair in the old graph. Only former neighbors may have arcs to or from the new pairs resulting from the transformation. Regarding neighbors in the graphs also suffices when performing the unifications required for narrowing and instantiation. In this way, the transformations can be performed efficiently. Recall that one should always regard SCCs first and afterwards, one builds new SCCs from the remaining pairs which were not strictly decreasing (Sect. 2) [16]. Of course, these pairs may already have been transformed during the (innermost) termination proof of the SCC. So this approach has the advantage that one never repeats transformations for the same dependency pairs.

## 6 Computing Argument Filterings

In the dependency pair approach we may apply an argument filtering $\pi$ to a set of constraints before starting an orientation attempt with a reduction pair. However, the number of possible argument filterings is exponential in the arities of the function symbols. We now show how to search for suitable argument filterings efficiently in the improved dependency pair approach of Thm. 9 and Thm. 13. More precisely, for every cycle $\mathcal{P}$, we show how to compute small subsets $\Pi^{t}(\mathcal{P})$ and $\Pi^{i}(\mathcal{P})$ of argument filterings which contain all filterings which could possibly satisfy the constraints for termination or innermost termination, respectively. A corresponding algorithm was presented in [16] for termination
proofs w.r.t. Thm. 8. However, we now develop such an algorithm for the improved versions of the dependency pair approach from Thm. 9 and Thm. 13. In particular for innermost termination (Thm. 13), the algorithm is considerably more involved since the set of constraints depends on the argument filtering used. Moreover, instead of treating constraints separately as in [16], we process them according to an efficient depth-first strategy.

Let $\mathcal{R} \mathcal{P}$ be a class of reduction pairs describing the particular base order used (e.g., $\mathcal{R} \mathcal{P}$ may contain all LPOs with arbitrary precedences or all recursive path orders with status, etc.). For any set of dependency pairs $\mathcal{P}, \Pi(\mathcal{P})$ denotes the set of all argument filterings where at least one dependency pair in $\mathcal{P}$ is strictly decreasing and the remaining ones are weakly decreasing w.r.t. some reduction pair in $\mathcal{R} \mathcal{P}$. When referring to "dependency pairs", we also permit pairs resulting from dependency pairs by narrowing, rewriting, or instantiation.

We use the approach of [16] to consider partial argument filterings, i.e., filterings which are only defined on a subset of the signature. For example, in a term $f(g(x), y)$, if $\pi(f)=[2]$, then we do not have to determine $\pi(g)$, since all occurrences of $g$ are filtered away. Thus, we leave argument filterings as undefined as possible and permit the application of $\pi$ to a term $t$ whenever $\pi$ is sufficiently defined for $t$. More precisely, any partial argument filtering $\pi$ is sufficiently defined for a variable $x$. So the the domain of $\pi$ may even be empty, i.e., $D O M(\pi)=\varnothing$. An argument filtering $\pi$ is sufficiently defined for a term $f\left(t_{1}, \ldots, t_{n}\right)$ iff $f \in D O M(\pi)$ and $\pi$ is sufficiently defined for all $t_{i}$ with $i \in \mathcal{R e g P o s} \pi(f)$. An argument filtering is sufficiently defined for a set of terms $T$ iff it is sufficiently defined for all terms in $T$. To compare argument filterings which only differ in their domain $D O M$, we introduce a relation " $\sqsubseteq$ ". Then $\Pi(\mathcal{P})$ should only contain $\sqsubseteq$-minimal elements, i.e., if $\pi^{\prime} \in \Pi(\mathcal{P})$, then $\Pi(\mathcal{P})$ does not contain any $\pi \sqsubset \pi^{\prime}$. Of course, all argument filterings in $\Pi(\mathcal{P})$ must be sufficiently defined for the terms in the dependency pairs of $\mathcal{P}$.

Definition 20 ( $\sqsubseteq$ and $\Pi(\mathcal{P})$ ) For two (partial) argument filterings, we define $\pi \sqsubseteq \pi^{\prime}$ iff $\operatorname{DOM}(\pi) \subseteq D O M\left(\pi^{\prime}\right)$ and $\pi(f)=\pi^{\prime}(f)$ for all $f \in D O M(\pi)$. For a set $\mathcal{P}$ of dependency pairs, let $\Pi(\mathcal{P})$ consist of all $\sqsubseteq$-minimal elements of $\{\pi \mid$ there is $a(\succsim, \succ) \in \mathcal{R} \mathcal{P}$ such that $\pi(s) \succ \pi(t)$ for at least one $s \rightarrow t \in \mathcal{P}$ and $\pi(s) \succsim \pi(t)$ for all other $s \rightarrow t \in \mathcal{P}\}$.

We now define a superset $\Pi^{t}(\mathcal{P})$ of all argument filterings where the constraints (a) and (b) for termination of the cycle $\mathcal{P}$ are satisfied by some reduction pair of $\mathcal{R} \mathcal{P}$. So only these argument filterings have to be regarded when automating Thm. 9. To this end, we have to extend partial argument filterings.

Definition $21\left(E x_{f}, \Pi^{t}(\mathcal{P})\right.$ ) For a partial argument filtering $\pi$ and $f \in \mathcal{D}$, $E x_{f}(\pi)$ consists of all $\sqsubseteq$-minimal argument filterings $\pi^{\prime}$ such that $\pi \sqsubseteq \pi^{\prime}$ and such that there is a $(\succsim, \succ) \in \mathcal{R} \mathcal{P}$ with $\pi^{\prime}(l) \succsim \pi^{\prime}(r)$ for all $l \rightarrow r \in R l s(f)$. For a set $\Pi$ of filterings, let $E x_{f}(\Pi)=\bigcup_{\pi \in \Pi} E x_{f}(\pi)$. If $\mathcal{P}$ originates from $\operatorname{DP}\left(\mathcal{R}_{i}\right)$ by t-narrowing and $t$-instantiation and $\left\{f_{1}, \ldots, f_{k}\right\}$ are $\mathcal{R}_{i}^{\prime}$ 's defined symbols, then $\Pi^{t}(\mathcal{P})=E x_{f_{k}}\left(\ldots E x_{f_{1}}(\Pi(\mathcal{P})) \ldots\right)$.

We compute $\Pi^{t}(\mathcal{P})$ by depth-first search. So we start with some $\pi \in \Pi(\mathcal{P})$ and extend it to a minimal $\pi^{\prime}$ such that the $f_{1}$-rules are weakly decreasing. Then $\pi^{\prime}$ is extended such that the $f_{2}$-rules are weakly decreasing, etc. Here, $f_{1}$ is considered before $f_{2}$ if $f_{1}>_{d} f_{2}$. When we have $\Pi^{t}(\mathcal{P})$ 's first element $\pi_{1}$, we check whether Constraints (a) and (b) of Thm. 9 are satisfiable with $\pi_{1}$. In case of success, we do not compute further elements of $\Pi^{t}(\mathcal{P})$. Only if the constraints are not satisfiable with $\pi_{1}$, we determine $\Pi^{t}(\mathcal{P})$ 's next element, etc. The advantage of this approach is that $\Pi(\mathcal{P})$ is usually rather small, since it only contains argument filterings that satisfy a strict inequality.

For innermost termination, the set of constraints to be satisfied depends on the argument filtering used. If $f \geq_{d} g$, then when orienting the rules of $f$, we do not necessarily have to orient the rules of $g$ as well, since all occurrences of $g$ in $f$-rules may have been deleted by the argument filtering, cf. Thm. 13. To formalize this, we define a relation " $\vdash \mathcal{P}$ " on sets of argument filterings. Let us extend $\mathcal{R e g P o s}{ }_{\pi}$ to partial argument filterings by defining $\mathcal{R e g P o s}_{\pi}(f)=\varnothing$ for all $f \notin \operatorname{DOM}(\pi)$. Now $\mathcal{U}(\mathcal{P}, \pi)$ is also defined for partial filterings by simply disregarding all subterms of function symbols where $\pi$ is not defined.

For a partial argument filtering $\pi$, whenever $R l s(f)$ is included in the usable rules $\mathcal{U}(\mathcal{P}, \pi)$ for the cycle $\mathcal{P}$, then the relation " $\vdash_{\mathcal{P}}$ " can extend $\pi$ in order to make the $f$-rules weakly decreasing. We label each argument filtering by the set of those function symbols whose rules are already guaranteed to be weakly decreasing.

Definition $22\left(\vdash_{\mathcal{P}}\right)$ Each argument filtering $\pi$ is labelled with a set $\mathcal{G} \subseteq \mathcal{D}$ and we denote a labelled argument filtering by $\pi_{\mathcal{G}}$. For sets of labelled argument filterings, we define the relation " $\vdash_{\mathcal{P}}$ ": $\uplus \uplus\left\{\pi_{\mathcal{G}}\right\} \vdash_{\mathcal{P}} \Pi \cup\left\{\pi_{\mathcal{G} \cup\{f\}}^{\prime} \mid \pi^{\prime} \in E x_{f}(\pi)\right\}$, if $f \in \mathcal{D} \backslash \mathcal{G}$ and $\operatorname{Rls}(f) \subseteq \mathcal{U}(\mathcal{P}, \pi)$.

When proving innermost termination, we will only regard argument filterings that result from $\Pi(\mathcal{P})$ by applying $\vdash_{\mathcal{P}}$-reductions as long as possible. In order to prove that normal forms w.r.t. $\vdash_{\mathcal{P}}$ are unique, we need the following lemma. It states that $E x_{f}(\pi)$ always consists of pairwise incompatible argument filterings. Here, two argument filterings $\pi_{1}$ and $\pi_{2}$ are compatible if $\pi_{1}(f)=\pi_{2}(f)$ for all $f \in \operatorname{DOM}\left(\pi_{1}\right) \cap \operatorname{DOM}\left(\pi_{2}\right)$, cf. [16].

Lemma 23 (Incompatibility) Let $T$ be a finite set of terms.
(a) Let $\pi, \pi_{1}, \pi_{2}$ be (partial) argument filterings. Let $\pi_{1}, \pi_{2}$ be elements of $\left\{\pi^{\prime} \mid \pi \sqsubseteq\right.$ $\pi^{\prime}$ and $\pi^{\prime}$ is sufficiently defined for $\left.T\right\}$, where $\pi_{1}$ is $a \sqsubseteq$-minimal element of this set. If $\pi_{1}$ and $\pi_{2}$ are compatible, then $\pi_{1} \sqsubseteq \pi_{2}$.
(b) If $\pi_{1}, \pi_{2} \in E x_{f}(\pi)$ with $\pi_{1} \neq \pi_{2}$, then $\pi_{1}$ and $\pi_{2}$ are incompatible, i.e., Ex $f_{f}(\pi)$ consists of pairwise incompatible argument filterings.
(c) If $\Pi$ consists of pairwise incompatible argument filterings, then $E x_{f}(\Pi)$ consists of pairwise incompatible argument filterings as well.

Proof. (a) We perform induction on $T$ using the multiset version of the proper subterm relation. If $T=\varnothing$, then the only minimal extension of $\pi$ that is sufficiently defined for $T$ is $\pi_{1}=\pi$. Hence, $\pi_{1}=\pi \sqsubseteq \pi_{2}$.
Next let $T=T^{\prime} \uplus\{x\}$ for a variable $x$. Clearly, both $\pi_{1}$ and $\pi_{2}$ are also sufficiently defined for $T^{\prime}$ and moreover, $\pi_{1}$ is a minimal extension of $\pi$ that is sufficiently defined for $T^{\prime}$. Thus, the claim follows from the induction hypothesis.
If $T=T^{\prime} \uplus\left\{f\left(t_{1}, \ldots, t_{n}\right)\right\}$, then $f \in \operatorname{DOM}\left(\pi_{1}\right)$. Let $T^{\prime \prime}=T^{\prime} \cup\left\{t_{i} \mid i \in\right.$ $\left.\operatorname{RegPos}_{\pi_{1}}(f)\right\}$. Both $\pi_{1}$ and $\pi_{2}$ are sufficiently defined for $T^{\prime \prime}$ (for $\pi_{2}$ this follows from $\pi_{2}(f)=\pi_{1}(f)$ by compatibility of $\pi_{1}$ and $\left.\pi_{2}\right)$. If $\pi_{1}$ is a minimal extension of $\pi$ that is sufficiently defined for $T^{\prime \prime}$, then the claim is implied by the induction hypothesis. Otherwise, we have $f \notin D O M(\pi)$ and we obtain the following minimal extension $\pi_{1}^{\prime}$ of $\pi$ that is sufficiently defined for $T^{\prime \prime}$ : $\operatorname{DOM}\left(\pi_{1}^{\prime}\right)=\operatorname{DOM}\left(\pi_{1}\right) \backslash\{f\}$ and $\pi_{1}^{\prime}(g)=\pi_{1}(g)$ for all $g \in \operatorname{DOM}\left(\pi_{1}^{\prime}\right)$. Then the induction hypothesis implies $\pi_{1}^{\prime} \sqsubseteq \pi_{2}$. Since $\pi_{1}$ only differs from $\pi_{1}^{\prime}$ on the function symbol $f$ and since $\pi_{1}(f)=\pi_{2}(f)$, we obtain $\pi_{1} \sqsubseteq \pi_{2}$.
(b) Let $\pi_{1}, \pi_{2} \in E x_{f}(\pi)$ be compatible. As both filterings are minimal extensions of $\pi$ that are sufficiently defined for the terms on left- or right-hand sides of rules from $\operatorname{Rls}(f)$, we use (a) to conclude both $\pi_{1} \sqsubseteq \pi_{2}$ and $\pi_{2} \sqsubseteq \pi_{1}$, which implies $\pi_{1}=\pi_{2}$.
(c) Let $\pi_{1} \in E x_{f}\left(\pi_{1}^{\prime}\right)$ and $\pi_{2} \in E x_{f}\left(\pi_{2}^{\prime}\right)$, where $\pi_{1}^{\prime}, \pi_{2}^{\prime} \in \Pi$. If $\pi_{1}^{\prime}=\pi_{2}^{\prime}$, then $\pi_{1}$ and $\pi_{2}$ are incompatible by (b). Otherwise $\pi_{1}^{\prime} \neq \pi_{2}^{\prime}$, and by the assumption about $\Pi$ we obtain that $\pi_{1}^{\prime}$ and $\pi_{2}^{\prime}$ are incompatible. As $\pi_{1}^{\prime} \sqsubseteq \pi_{1}$ and $\pi_{2}^{\prime} \sqsubseteq \pi_{2}$, this implies that $\pi_{1}$ and $\pi_{2}$ are incompatible as well.

The next theorem shows the desired properties of the relation $\vdash_{\mathcal{P}}$.

Theorem $24 \vdash_{\mathcal{P}}$ is terminating and confluent.

Proof. The termination of $\vdash_{\mathcal{P}}$ is obvious as the labellings increase in every $\vdash_{\mathcal{P}}$ step. Hence for confluence, it suffices to show local confluence. The only crucial non-determinism in the definition of $\vdash_{\mathcal{P}}$ is the choice of $f$. Suppose that $f_{0}, f_{1} \in$ $\mathcal{D} \backslash \mathcal{G}$ with $f_{0} \neq f_{1}$ and $R l s\left(f_{0}\right) \cup R l s\left(f_{1}\right) \subseteq \mathcal{U}(\mathcal{P}, \pi)$. This leads to two possible reduction steps

$$
\begin{array}{ll}
\Pi \uplus\left\{\pi_{\mathcal{G}}\right\} \vdash_{\mathcal{P}} \Pi \cup \Pi_{0}, & \text { where } \Pi_{0}=\left\{\pi_{\mathcal{G} \cup\left\{f_{0}\right\}}^{0} \mid \pi^{0} \in E x_{f_{0}}(\pi)\right\} \\
\Pi \uplus\left\{\pi_{\mathcal{G}}\right\} \vdash_{\mathcal{P}} \Pi \cup \Pi_{1}, & \text { where } \Pi_{1}=\left\{\pi_{\mathcal{G} \cup\left\{f_{1}\right\}}^{1} \mid \pi^{1} \in E x_{f_{1}}(\pi)\right\}
\end{array}
$$

Note that $\mathcal{U}(\mathcal{P}, \pi) \subseteq \mathcal{U}\left(\mathcal{P}, \pi^{i}\right)$ holds for all $\pi^{i} \in E x_{f_{i}}(\pi)$. Thus for all filterings $\pi_{\mathcal{G} \cup\left\{f_{i}\right\}}^{i} \in \Pi_{i}$, we have $f_{1-i} \in \mathcal{D} \backslash\left(\mathcal{G} \cup\left\{f_{i}\right\}\right)$ and $\operatorname{Rls}\left(f_{1-i}\right) \subseteq \mathcal{U}\left(\mathcal{P}, \pi^{i}\right)$. Hence, we can build the following reductions (where we also allow the application of $E x_{f}$
to labelled argument filterings by simply ignoring their labels).

$$
\begin{array}{rlll}
\Pi \cup \Pi_{0} & \stackrel{\left|\Pi_{0}\right|}{\vdash} \mathcal{P}^{\prime} & \left(\Pi \backslash \Pi_{0}\right) & \cup\left\{\pi_{\mathcal{G} \cup\left\{f_{0}, f_{1}\right\}}^{\prime} \mid \pi^{\prime} \in E x_{f_{1}}\left(E x_{f_{0}}(\pi)\right)\right\} \\
& \stackrel{\left|\Pi \cap \Pi_{1}\right|}{\vdash} \mathcal{P} & \left(\Pi \backslash\left(\Pi_{0} \cup \Pi_{1}\right)\right) \cup\left\{\pi_{\mathcal{G} \cup\left\{f_{0}, f_{1}\right\}}^{\prime} \mid\right. & \left.\pi^{\prime} \in \operatorname{Ex}_{f_{1}}\left(E x_{f_{0}}(\pi)\right)\right\} \\
& \cup\left\{\pi_{\mathcal{G} \cup\left\{f_{1}, f_{0}\right\}}^{\prime} \mid \pi^{\prime} \in E x_{f_{0}}\left(\Pi \cap \Pi_{1}\right)\right\}
\end{array}
$$

and

$$
\begin{array}{rlll}
\Pi \cup \Pi_{1} & \stackrel{\left|\Pi_{1}\right|}{\vdash} \mathcal{P} & \left(\Pi \backslash \Pi_{1}\right) & \cup\left\{\pi_{\mathcal{G} \cup\left\{f_{1}, f_{0}\right\}}^{\prime} \mid \pi^{\prime} \in E x_{f_{0}}\left(\operatorname{Ex}_{f_{1}}(\pi)\right)\right\} \\
\stackrel{\left|\Pi \cap \Pi_{0}\right|}{\vdash} \mid & \left(\Pi \backslash\left(\Pi_{1} \cup \Pi_{0}\right)\right) \cup\left\{\pi_{\mathcal{G} \cup\left\{f_{1}, f_{0}\right\}}^{\prime} \mid \pi^{\prime} \in E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right)\right\} \\
& \cup\left\{\pi_{\mathcal{G} \cup\left\{f_{0}, f_{1}\right\}}^{\prime} \mid \pi^{\prime} \in E x_{f_{1}}\left(\Pi \cap \Pi_{0}\right)\right\}
\end{array}
$$

where $E x_{f_{0}}\left(\Pi \cap \Pi_{1}\right) \subseteq E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right)$ and $E x_{f_{1}}\left(\Pi \cap \Pi_{0}\right) \subseteq E x_{f_{1}}\left(E x_{f_{0}}(\pi)\right)$. Hence, the missing step to finish this proof is to show $E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right)=E x_{f_{1}}\left(E x_{f_{0}}(\pi)\right)$. Because of symmetry, it suffices to prove $E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right) \subseteq E x_{f_{1}}\left(E x_{f_{0}}(\pi)\right)$. To this end, we only have to show that for every $\pi_{01} \in E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right)$ there exists a $\pi_{10} \in E x_{f_{1}}\left(E x_{f_{0}}(\pi)\right)$ with $\pi_{10} \sqsubseteq \pi_{01}$. The reason is that in an analogous way one can show that for $\pi_{10}$ there also exists a $\pi_{01}^{\prime} \in E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right)$ with $\pi_{01}^{\prime} \sqsubseteq \pi_{10}$. Hence, we have $\pi_{01}^{\prime} \sqsubseteq \pi_{10} \sqsubseteq \pi_{01}$ and by Lemma 23 (b) and (c), this implies $\pi_{01}^{\prime}=\pi_{10}=\pi_{01}$ 。

Let $\pi_{01} \in E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right)$. By the definition of $E x$, there must be a $\pi_{1} \in$ $E x_{f_{1}}(\pi)$ and a reduction pair $(\succsim, \succ) \in \mathcal{R} \mathcal{P}$ with $\pi_{1} \sqsubseteq \pi_{01}$ and $\pi_{01}(l) \succsim \pi_{01}(r)$ for all $l \rightarrow r \in \operatorname{Rls}\left(f_{0}\right)$. As $\pi_{1} \in E x_{f_{1}}(\pi)$, we may conclude in the same way that $\pi \sqsubseteq \pi_{1}$ and $\pi_{1}(l) \succsim^{\prime} \pi_{1}(r)$ for all $f_{1}$-rules and some reduction pair $\left(\succsim^{\prime}, \succ^{\prime}\right) \in \mathcal{R} \mathcal{P}$. Since $\pi \sqsubseteq \pi_{01}$ and since the $f_{0}$-rules can be oriented in a weakly decreasing way using $\pi_{01}$, there exists a $\pi_{0} \in E x_{f_{0}}(\pi)$ with $\pi \sqsubseteq \pi_{0} \sqsubseteq \pi_{01}$ such that the $f_{0^{-}}$ rules can also be oriented using $\pi_{0}$. Since $\pi_{0} \sqsubseteq \pi_{01}$ and since the $f_{1}$-rules can be oriented with $\pi_{01}$, there is a $\pi_{10} \in E x_{f_{1}}\left(\pi_{0}\right)$ with $\pi_{0} \sqsubseteq \pi_{10} \sqsubseteq \pi_{01}$ such that $\pi_{10}$ also permits an orientation of the $f_{1}$-rules. As explained above, this suffices to prove $E x_{f_{0}}\left(E x_{f_{1}}(\pi)\right) \subseteq E x_{f_{1}}\left(E x_{f_{0}}(\pi)\right)$.

Now we can define the set of argument filterings that are regarded for innermost termination proofs.

Definition $25\left(\Pi^{i}(\mathcal{P})\right.$ ) Let $N f_{\vdash_{\mathcal{P}}}(\Pi)$ denote the normal form of $\Pi$ w.r.t. $\vdash_{\mathcal{P}}$. Then we define $\Pi^{i}(\mathcal{P})=N f_{\vdash_{\mathcal{P}}}\left(\left\{\pi_{\varnothing} \mid \pi \in \Pi(\mathcal{P})\right\}\right)$.

To compute $\Pi^{i}(\mathcal{P})$, we again start with some $\pi \in \Pi(\mathcal{P})$. Now $\pi$ only has to be extended in order to make the rules for a symbol $f$ weakly decreasing if the $f$-rules are contained in $\mathcal{U}(\mathcal{P}, \pi)$. If by this extension, the rules for some new symbol $g$ become usable, then a subsequent extension with $E x_{g}$ is also necessary, etc.

Thm. 26 states that by $\Pi^{t}(\mathcal{P})\left(\right.$ resp. $\Pi^{i}(\mathcal{P})$ ), one indeed obtains all argument filterings which could possibly solve the dependency pair constraints. Here, $\mathcal{P}$ may also result from narrowing, rewriting, and instantiating dependency pairs. In this way the set of argument filterings is reduced dramatically and thus, efficiency is increased. For example, for a TRS from [3, Ex. 3.11] computing quicksort, $\Pi^{t}(\mathcal{P})$ reduces the number of argument filterings from more than 26 million to 3734 and with $\Pi^{i}(\mathcal{P})$ we obtain a reduction from more than 1.4 million to 783 .

Theorem 26 Let $\mathcal{P}$ be a cycle. If the constraints (a) and (b) of Thm. 9 for termination are satisfied for some reduction pair from $\mathcal{R} \mathcal{P}$ and argument filtering $\pi$, then $\pi^{\prime} \sqsubseteq \pi$ for some $\pi^{\prime} \in \Pi^{t}(\mathcal{P})$. If the constraints (c) and (d) of Thm. 13 for innermost termination are satisfied for some reduction pair from $\mathcal{R} \mathcal{P}$ and argument filtering $\pi$, then $\pi^{\prime} \sqsubseteq \pi$ for some $\pi^{\prime} \in \Pi^{i}(\mathcal{P})$.

Proof. Let $\pi$ be an argument filtering and let $(\succsim, \succ) \in \mathcal{R} P$ be a reduction pair that solve the constraints (a) and (b) from Thm. 9 or the constraints (c) and (d) from Thm. 13 for a cycle $\mathcal{P}$, respectively.

We first consider the termination case. There must be a minimal argument filtering $\pi_{0} \in \Pi(\mathcal{P})$ with $\pi_{0} \sqsubseteq \pi$ that solves the constraints in (a) using ( $\succsim, \succ$ ). Let $\mathcal{P}$ originate from $D P\left(\mathcal{R}_{i}\right)$, where $\mathcal{R}_{i}^{\prime}$ has the defined symbols $\left\{f_{1}, \ldots, f_{k}\right\}$. As $\pi_{0} \sqsubseteq \pi$ and $\pi(l) \succsim \pi(r)$ for all $f_{1}$-rules $l \rightarrow r$, there must be a filtering $\pi_{1} \in E x_{f_{1}}\left(\pi_{0}\right)$ with $\pi_{1} \sqsubseteq \pi$. We continue in this way and obtain an argument filtering $\pi_{k} \in E x_{f_{k}}\left(\ldots E x_{f_{1}}(\Pi(\mathcal{P})) \ldots\right)=\Pi^{t}(\mathcal{P})$ with $\pi_{k} \sqsubseteq \pi$.

In the innermost case, let $\Pi(\mathcal{P})=\Pi_{0} \vdash_{\mathcal{P}} \Pi_{1} \vdash_{\mathcal{P}} \ldots \vdash_{\mathcal{P}} \Pi_{n}=\Pi^{i}(\mathcal{P})$ be a $\vdash_{\mathcal{P}}$-reduction to normal form. We show that for all $0 \leq j \leq n$ there is a $\pi_{j} \in \Pi_{j}$ with $\pi_{j} \sqsubseteq \pi$ by induction on $j$. For $j=0$, since $\pi$ solves the constraints in (c), by definition there is again a minimal argument filtering $\pi_{0} \in \Pi(\mathcal{P})$ with $\pi_{0} \sqsubseteq \pi$. For $j>0$, we assume that there is a $\pi_{j-1} \in \Pi_{j-1}$ with $\pi_{j-1} \sqsubseteq \pi$. Thus, we either have $\pi_{j-1} \in \Pi_{j}$ as well or else, $\Pi_{j}$ results from $\Pi_{j-1}$ by replacing $\pi_{j-1}$ by all elements of $E x_{f}\left(\pi_{j-1}\right)$ for some $f$ with $R l s(f) \subseteq \mathcal{U}\left(\mathcal{P}, \pi_{j-1}\right)$. Since $\pi_{j-1} \sqsubseteq \pi$, we have $\mathcal{U}\left(\mathcal{P}, \pi_{j-1}\right) \subseteq \mathcal{U}(\mathcal{P}, \pi)$ and thus, $\pi$ also makes the $f$-rules weakly decreasing. This implies that there must be a $\pi_{j} \in E x_{f}\left(\pi_{j-1}\right) \subseteq \Pi_{j}$ with $\pi_{j} \sqsubseteq \pi$.

The converse directions of this theorem do not hold, since in the computation of $\Pi^{t}(\mathcal{P})$ and $\Pi^{i}(\mathcal{P})$, when extending argument filterings, one does not take the orders into account. So even if $E x_{f}\left(E x_{g}(\ldots)\right) \neq \varnothing$, it could be that there is no reduction pair such that both $f$ - and $g$-rules are weakly decreasing w.r.t. the same reduction pair.

The technique of this section can be extended by storing both argument filterings and corresponding parameters of the order in the sets $\Pi(\mathcal{P})$ and $E x_{f}(\ldots)$. For example, if $\mathcal{R} \mathcal{P}$ is the set of all LPOs, then $\Pi(\mathcal{P})$ would now contain all (minimal) pairs of argument filterings $\pi$ and precedences such that $\pi(s) \succ_{l p o} \pi(t)$ resp. $\pi(s) \succsim_{l p o} \pi(t)$ holds for $s \rightarrow t \in \mathcal{P}$. When extending argument filterings, one would also have to extend the corresponding precedence. Of course, such
an extension is only permitted if the extended precedence is still irreflexive (and hence, well founded). Then, $\Pi^{t}(\mathcal{P})\left(\right.$ resp. $\left.\Pi^{i}(\mathcal{P})\right)$ is non-empty iff the constraints for (innermost) termination are satisfiable for $\mathcal{P}$. Thus, after computing $\Pi^{t}(\mathcal{P})$ resp. $\Pi^{i}(\mathcal{P})$, no further checking of orders and constraints is necessary anymore. This variant is particularly suitable for orders with few parameters like LPO.

## 7 Heuristics

Now we present heuristics to improve the efficiency of the approach. They concern the search for argument filterings (Sect. 7.1) and for base orders (Sect. 7.2 and 7.3). In contrast to the improvements of the preceding sections, these heuristics affect the power of the method, i.e., there exist examples whose (innermost) termination can no longer be proved when following the heuristics.

### 7.1 Type Inference for Argument Filterings

In Sect. 6, we have shown how to reduce the set of possible argument filterings by removing filterings which cannot satisfy the constraints for (innermost) termination using dependency pairs. However, since the resulting sets $\Pi^{t}(\mathcal{P})$ and $\Pi^{i}(\mathcal{P})$ can still be large, it is often advantageous to reduce them even further. To this end, we have developed the following heuristic based on type inference.

In natural examples, termination of a function is usually due to the decrease of arguments of the same type. Of course, this type may be different for the different functions in a TRS. So we use a (monomorphic) type inference algorithm to transform a TRS into a sorted TRS (i.e., a TRS with rules $l \rightarrow r$ where $l$ and $r$ are well-typed terms of the same type). As a good heuristic to reduce the set of possible argument filterings further, one can require that for every symbol $f$, either no argument position is eliminated or all non-eliminated argument positions are of the same type. In other words, if $f$ is $n$-ary, then $\pi(f)=[1, \ldots, n]$, $\pi(f) \in\{1, \ldots, n\}$, or $\pi(f)=\left[i_{1}, \ldots, i_{k}\right]$ where the argument positions $i_{1}, \ldots, i_{k}$ all have the same type. Our experiments show that all examples in the collections of $[3,9,27]$ that can be solved using LPO as a base order can still be solved when using this heuristic.

### 7.2 Embedding Order for Dependency Pairs

To increase efficiency in our depth-first algorithm of Sect. 6, a successful heuristic is to only use the embedding order when orienting the constraints $\pi(s) \succ \pi(t)$ and $\pi(s) \succsim \pi(t)$ for dependency pairs $s \rightarrow t$. Only for constraints of the form $\pi(l) \succsim \pi(r)$ for rules $l \rightarrow r$, one may apply more complicated quasi-orders e.g., LPO, $\mathrm{RPO}(\mathrm{S})$, or polynomial orders. The advantage of this approach is that now $\Pi(\mathcal{P})$ is much smaller than when using more powerful orders. Thus, the depthfirst search starting with $\Pi(\mathcal{P})$ can be performed very quickly. Our experiments show that due to the improvements in Sect. 3 and 4, this heuristic succeeds for more than $96 \%$ of those examples from $[3,9,27]$ where a full LPO was successful, while reducing runtimes by at least $58 \%$.

### 7.3 Bottom-Up Heuristic

To determine argument filterings in Sect. 6, we start with the dependency pairs and treat the constraints for rules afterwards, where $f$-rules are considered before $g$-rules if $f>_{d} g$. In contrast, now we suggest a bottom-up approach which starts with determining an argument filtering for constructors and then moves upwards through the recursion hierarchy where $g$ is treated before $f$ if $f>_{d} g$. While in Sect. 6, we determined sets of argument filterings, now we only determine one single argument filtering, even if several ones are possible. To obtain an efficient technique, no backtracking takes place, i.e., if at some point one selects the "wrong" argument filtering, then the proof can fail.

More precisely, we first guess an argument filtering $\pi$ which is only defined for constructors. For every $n$-ary constructor $c$ we define $\pi(c)=[1, \ldots, n]$ or we let $\pi$ filter away all argument of $c$ that do not have the same type as $c$ 's result. Afterwards, for every function symbol $f$, we try to extend $\pi$ on $f$ such that $\pi(l) \succsim \pi(r)$ for all $f$-rules $l \rightarrow r$. We consider functions according to the recursion hierarchy $>_{d}$. So when extending $\pi$ on $f, \pi$ is already defined on all $g<_{d} f$. Among the extensions of $\pi$ which permit an orientation of the $f$-rules, we choose $\pi(f)$ such that it eliminates as many arguments of $f$ as possible. Of course, this is just one of the potential argument filterings for $f$. If we have chosen the "wrong" argument filtering for $f$, the (innermost) termination proof might fail, although there would have been a solution with a different argument filtering. If we are not able to orient the rules of $f$, then we mark $f$ as not orientable. Finally, after having treated all rules, the filtering is extended to the tuple symbols by trying to orient the dependency pairs as well (where at least one dependency pair must be strictly decreasing). Of course, this extension is done separately for every SCC or cycle, respectively.

In termination proofs, if $f \in \mathcal{R}_{j}$ is not orientable, then all symbols in $\mathcal{R}_{i} \geq_{d} \mathcal{R}_{j}$ as well as all dependency pairs resulting from $\mathcal{R}_{i} \geq_{d} \mathcal{R}_{j}$ are also not orientable. In innermost termination proofs, if $f$ is not orientable, then a symbol that depends on $f$ can still be orientable if one can extend the argument filtering in such a way that all occurrences of $f$ in its rules are eliminated. Similarly, dependency pairs can still be orientable if the argument filtering eliminates all occurrences of $f$. Thus, here the bottom-up approach has the advantage that we already know that certain argument positions must be eliminated when extending the argument filtering to new function symbols.

This algorithm can also be modified by determining both the argument filtering and the reduction pair step by step. For example, a successful option is to use linear polynomial orders with coefficients 0 and 1. By permitting the coefficient 0 , polynomial orders can also perform argument filtering, i.e., one does not have to use any extra argument filterings anymore. Again we consider two possibilities for the interpretation of constructors. One possibility is to map every $n$-ary constructor $c\left(x_{1}, \ldots, x_{n}\right)$ to the polynomial $1+x_{1}+\ldots+x_{n}$ if $n>0$ and to 0 , otherwise. The other possibility is to map every constructor $c\left(x_{1}, \ldots, x_{n}\right)$ to the polynomial $1+x_{i_{1}}+\ldots+x_{i_{k}}$ if $i_{1}, \ldots, i_{k}$ are the argument positions with the
same type as $c$ 's result and $k>0$. Otherwise, $c$ is mapped to 0 . When extending the polynomial interpretation to a function $f$, we have already determined the polynomial interpretation for all symbols $g<_{d} f$. Then, we try to find a minimal polynomial for $f$ such that the $f$-rules are weakly decreasing (i.e., as many coefficients as possible should be 0 ). The combination of the bottom-up algorithm with other orders (e.g., LPO) works in a similar way. Here, one always determines a minimal precedence which may be extended when proceeding to the next function symbol in the recursion hierarchy.

The bottom-up algorithm reduces the search space enormously. The number of TRSs from [3, 9, 27] where the bottom-up algorithm succeeds is $94 \%$ of the number achieved by the full dependency pair approach with LPO, but runtime is reduced to less than $18 \%$.

## 8 Conclusion and Implementation in the System AProVE

We have presented improvements of the dependency pair approach which significantly reduce the sets of constraints $\pi(l) \succsim \pi(r)$ for both termination and innermost termination proofs. Moreover, we extended the applicability of dependency pair transformations and developed a criterion to ensure that their application is terminating without compromising the power of the approach in almost all examples. To implement the approach, we have given an algorithm for computing argument filterings which is tailored to the improvements presented before. Finally, we have developed heuristics to increase efficiency which proved successful in large case studies.

We implemented these results in the system AProVE (́Automated Program Verification Environment), which is available at http://www-i2.informatik. rwth-aachen.de/AProVE. The tool is written in Java and proofs can be performed both in a fully automated or in an interactive mode via a graphical user interface. To combine the heuristics of Sect. 7, for every SCC $\mathcal{P}$, AProVE offers the following combination algorithm which uses the heuristics as a pre-processing step and only calls the full dependency pair approach for cycles where the heuristics fail:

1. Safe transformations with Cases (1) and (2) of Def. 18
2. Bottom-up heuristic of Sect. 7.3
3. Heuristics of Sect. 7.1 and Sect. 7.2 with LPO as base order
4. Remaining safe transformations according to Def. 18.

If at least one transformation was applied, go back to 1.
5. Full dependency pair approach with RPO as base order

When the constraints for the SCC are solved, the algorithm is called recursively with the SCCs of those remaining pairs which were only weakly decreasing. We tested the combination algorithm on the collections of [3, 9, 27] (108 TRSs for termination, 151 TRSs for innermost termination). Our system succeeded on $96.6 \%$ of the innermost termination examples (including all of [3]) and on
93.5 \% of the examples for termination. The automated proof for the whole collection took 80 seconds for innermost termination and 27 seconds for termination. These results indicate that the contributions of the paper are indeed very useful in practice.

## A Empirical Results

We have implemented the results of this paper in our system AProVE and the following tables show the success rate and runtimes for the different techniques and heuristics. We have tested the system on the examples of [3, 9, 27] (108 TRSs for termination, 151 TRSs for innermost termination). In the tables, " S " stands for examples of Steinbach's collection [27] and "D" denotes examples of Dershowitz [9]. The remaining examples are taken from Chapter 3 and 4 of the collection of Arts and Giesl [3]. However for termination proofs, we did not regard the TRSs from Chapter 4 of [3], since many of them are only innermost terminating, but not terminating. Since some TRSs occur in several of these collections, we only consider each TRS once (for that reason, examples of [9] and [27] are not reconsidered if they also appear in [3]).

We have used AProVE in the following different settings:

- Normal is the method of Sect. $3-6$ with reduction pairs based on LPO or the embedding order. For the LPO we allow different symbols to be equal in the precedence. Moreover, when computing the sets $\Pi^{t}(\mathcal{P})$ and $\Pi^{i}(\mathcal{P})$, we determine both the argument filterings and the precedences of the LPO, as illustrated at the end of Sect. 6. However, in this setting, we do not apply the heuristics of Sect. 7.
- Old is like Normal, but it uses Thm. 8 instead of Thm. 9 and 13.
- Type is like Normal, but it uses the type inference heuristic of Sect. 7.1.
- Emb is like Normal, but it applies the heuristic to use the embedding order for dependency pairs (Sect. 7.2).
- Bottom-Up uses the bottom-up heuristic of Sect. 7.3 where we determine both the argument filtering and the reduction pair step by step. Here, for every SCC or cycle, the bottom-up algorithm may be applied several times. For
example, one may use linear polynomial orders with coefficients 0 and 1 , but if the constraints are not satisfied with the first possibility for interpreting constructors, then one can try the other possibility as illustrated in Sect. 7.3. In a similar way, one can use LPO instead of polynomial orders and regard the two possibilities for filtering constructors (no elimination of arguments or a filtering determined by type inference). Finally, it is also possible to combine both kinds of reduction pairs by first checking the two possibilities with polynomial orders and then checking the two possibilities with LPO, if the constraints for this cycle have not yet been solved. In this way, we obtained 3 different versions of the bottom-up algorithm where in the last version, the bottom-up algorithm may be applied at most four times for each cycle or SCC, respectively.
- Combi is the combination algorithm of Sect. 8 where we used the last version of the bottom-up algorithm described above.

The next two tables summarize the results of our experiments. In the "Power" column we give the number of examples where the proof attempt was successful. In square brackets we indicate the percentage of these examples compared to the number of all examples in the collection. In the "Time" column we give the overall runtime for running the system on all examples of the collection (also on the ones where the proof attempt failed). For each example we used a time-out of 30 seconds. The average time required for each example is given in square brackets. The detailed results of our experiments can be found at the end of this appendix.

| Algorithm | Order | Power | Time |
| :---: | :---: | :---: | :---: |
| Termination |  |  |  |
| Old | EMB | 52 [48.1 \%] | 110.8 s [1.0 s] |
| Normal | EMB | 64 [59.2 \%] | 113.1 s [1.0 s] |
| Old | LPO | 81 [75.0 \%] | 320.0 s [2.9 s] |
| Normal | LPO | 85 [78.7\%] | 246.3 s [2.2 s] |
| Innermost Termination |  |  |  |
| Old | EMB | 100 [66.2 \%] | 213.5 s [1.4 s] |
| Normal | EMB | 121 [80.1 \%] | 152.4 s [1.0 s] |
| Old | LPO | 128 [84.7 \%] | 412.1 s [2.7 s] |
| Normal | LPO | 131 [86.7 \%] | 353.9 s [2.3 s] |

The above table illustrates the usefulness of the results from Sect. 3 and 4 and shows that Thm. 9 and 13 indeed improve upon Thm. 8 in practice. If one uses simple reduction pairs like the embedding order where orientability can be checked very efficiently, then compared to Thm. 8, Thm. 9 and 13 increase power by more than $20 \%$ on the examples from [3, 9, 27]. For innermost termination, runtimes are decreased by about $28 \%$, while for termination one keeps approximately the same runtimes. If the reduction pairs are more complex (i.e., LPO),
then Thm. 9 and 13 significantly reduce runtime (by about $23 \%$ for termination and about $14 \%$ for innermost termination), while power is increased moderately.

| Algorithm | Orders | Power | Time |
| :---: | :---: | :---: | :---: |
| Termination |  |  |  |
| Normal | LPO | 85 [78.7 \%] | 246.3 s [2.2 s] |
| Type | LPO | 85 [78.7 \%] | 226.1 s [2.0 s] |
| Emb | LPO | 82 [75.9 \%] | 104.1 s [0.9 s] |
| Bottom-Up | LPO | 66 [61.1 \%] | 76.9 s [0.7 s] |
| Bottom-Up | Polo | 75 [69.4 \%] | 25.4 s [0.2 s] |
| Bottom-Up | Polo, LPO | 80 [74.0 \%] | $27.2 \mathrm{~s}[0.2 \mathrm{~s}]$ |
| Combi |  | 101 [93.5 \%] | 28.4 s [0.2 s] |
| Innermost Termination |  |  |  |
| Normal | LPO | 131 [86.7 \%] | 353.9 s [2.3 s] |
| Type | LPO | 131 [86.7 \%] | 316.3 s [2.0 s] |
| Emb | LPO | 128 [84.7\%] | 137.2 s [0.9 s] |
| Bottom-Up | LPO | 113 [74.8 \%] | 115.7 s [0.7 s] |
| Bottom-Up | Polo | 125 [82.7\%] | 60.6 s [0.4 s] |
| Bottom-Up | Polo, LPO | 126 [83.4 \%] | 63.2 s [0.4 s] |
| Combi |  | 146 [96.6 \%] | 86.1 s [0.5 s] |

This table illustrates the usefulness of the heuristics of Sect. 7 and the combination algorithm described in Sect. 8. The results show that the type inference heuristic on its own does not improve the performance very much, but it also does not reduce the set of examples where the method is successful. With the embedding order heuristic from Sect. 7.2 we only lose a few examples in comparison to the full algorithm, but we need less than half of the time. Using the bottom-up heuristics, there exist several examples where we are no longer able to prove (innermost) termination, but we are at least three times faster than with the full approach. We also see that using simple polynomial orders for the bottom-up heuristic is fast and successful. Finally, with the combined algorithm, we obtain the best of all methods. The algorithm is almost as fast as the bottomup algorithm and we get a success rate of over $93 \%$ for the examples from the collections of $[3,9,27]$.

The following tables give the detailed runtimes (in seconds, where " $\infty$ " denotes a time-out after 30 seconds) and results for the examples (where "OK" means that the proof succeeded and "-" means that the proof failed).

[^0]:    * Extended version of a paper from the Proceedings of the 10th International Conference on Logic for Programming, Artificial Intelligence and Reasoning (LPAR '03), Almaty, Kazakhstan, LNAI, Springer-Verlag, 2003.

[^1]:    ${ }^{1}$ To see this, consider Toyama's TRS [30] where $\mathcal{R}_{1}=\mathcal{R}_{1}^{\prime}=\{\mathrm{f}(0,1, x) \rightarrow \mathrm{f}(x, x, x)\}$ and $\mathcal{R}_{2}=\mathcal{R}_{2}^{\prime}=\{\mathrm{g}(x, y) \rightarrow x, \mathrm{~g}(x, y) \rightarrow y\}$. $\mathcal{R}_{1}^{\prime}$ 's and $\mathcal{R}_{2}^{\prime}$ 's dependency graphs are empty, whereas the dependency graph of $\mathcal{R}=\mathcal{R}_{1} \cup \mathcal{R}_{2}$ has a cycle. Hence, if one only considers the graphs of $\mathcal{R}_{1}^{\prime}$ and $\mathcal{R}_{2}^{\prime}$, one could falsely prove termination.
    ${ }^{2}$ It suffices if $\succsim$ is extendable to $c(x, y) \succsim x, c(x, y) \succsim y$ and $(\succsim, \succ)$ is still a reduction pair.

[^2]:    ${ }^{3}$ Of course, the constraints depend on the approximation of the (innermost) dependency graph. Here, we use the estimation of Def. 5 .
