# Term rewriting

Hans Zantema Termination of term graph rewriting

ヘロン 人間 とくほと 人ほとう

æ

If t is a term, and  $\sigma$  maps variables to terms, then  $t\sigma$  is the term obtained from t by replacing every variable x by  $\sigma(x)$ 

If t is a term, and  $\sigma$  maps variables to terms, then  $t\sigma$  is the term obtained from t by replacing every variable x by  $\sigma(x)$ 

*Term rewriting* = if a subterm is of the shape  $\ell\sigma$  for some rule  $\ell \rightarrow r$ , then it may be replaced by  $r\sigma$ 

ヘロン 人間 とくほ とくほ とう

If t is a term, and  $\sigma$  maps variables to terms, then  $t\sigma$  is the term obtained from t by replacing every variable x by  $\sigma(x)$ 

*Term rewriting* = if a subterm is of the shape  $\ell\sigma$  for some rule  $\ell \rightarrow r$ , then it may be replaced by  $r\sigma$ 

This is a widely applied standard way of computation

For efficient implementation of terms and term rewriting a subterm occurring twice should be stored only once

・ロト ・回ト ・ヨト ・ヨト

э

For efficient implementation of terms and term rewriting a subterm occurring twice should be stored only once

回 と く ヨ と く ヨ と

For efficient implementation of terms and term rewriting a subterm occurring twice should be stored only once

In this way terms are represented by *DAGs* (directed acyclic graphs) rather than by trees

In rewriting DAGs it is natural not to duplicate dags

In rewriting DAGs it is natural not to duplicate dags

For instance, by

$$x * (y + z) \rightarrow (x * y) + (x * z)$$

in rewriting terms = trees, the subterm corresponding to x is duplicated, while in rewriting DAGs the subterm corresponding to x only gets an extra incoming arrow

・ 同 ト ・ ヨ ト ・ ヨ ト

In rewriting DAGs it is natural not to duplicate dags

For instance, by

$$x*(y+z) \rightarrow (x*y) + (x*z)$$

in rewriting terms = trees, the subterm corresponding to x is duplicated, while in rewriting DAGs the subterm corresponding to x only gets an extra incoming arrow

With the three rules

$$f(x, a, b) \rightarrow f(x, x, x), \ c \rightarrow a, \ c \rightarrow b$$

the infinite term reduction

$$f(c, a, b) \rightarrow f(c, c, c) \rightarrow f(c, a, c) \rightarrow f(c, a, b) \rightarrow \cdots$$

can not be mimicked in DAG rewriting without doing intermediate unsharing

・ 同 ト ・ ヨ ト ・ ヨ ト

-

If either the rewrite systems is non-duplicating, or it is orthogonal (no overlap between left hand sides), then every term rewriting reduction can be mimicked by DAG rewriting

・ 戸 ・ ・ ヨ ・ ・ ヨ ・

If either the rewrite systems is non-duplicating, or it is orthogonal (no overlap between left hand sides), then every term rewriting reduction can be mimicked by DAG rewriting

In all cases we assume the rewrite system is *left-linear* (no duplicate variables in left hand sides), otherwise it is not clear how to rewrite

・ 同 ト ・ 国 ト ・ 国 ト

If either the rewrite systems is non-duplicating, or it is orthogonal (no overlap between left hand sides), then every term rewriting reduction can be mimicked by DAG rewriting

In all cases we assume the rewrite system is *left-linear* (no duplicate variables in left hand sides), otherwise it is not clear how to rewrite

What happens if we allow graphs with cycles?

・ 同 ト ・ ヨ ト ・ ヨ ト

#### Term graphs

Such a graph is called a *term graph*, in which all nodes are labeled by operation symbols, and a node labeled by f of arity n has exactly n numbered outgoing edges

・ 同 ト ・ ヨ ト ・ ヨ ト

#### Term graphs

Such a graph is called a *term graph*, in which all nodes are labeled by operation symbols, and a node labeled by f of arity n has exactly n numbered outgoing edges

More precisely:

#### Definition

A term graph over a signature  $\Sigma$  is a triple (V, lab, succ) in which

- V is a finite set of nodes (vertices)
- lab :  $V \to \Sigma$  is a partial labeling function
- succ : V → V\* is the partial successor function having the same domain as lab, such that ∀v ∈ V : |succ(v)| = ar(lab(v))

< ロ > < 同 > < 回 > < 回 > < □ > <

### Term graphs

Such a graph is called a *term graph*, in which all nodes are labeled by operation symbols, and a node labeled by f of arity n has exactly n numbered outgoing edges

More precisely:

#### Definition

A term graph over a signature  $\Sigma$  is a triple (V, lab, succ) in which

- V is a finite set of nodes (vertices)
- lab :  $V \to \Sigma$  is a partial labeling function
- succ : V → V\* is the partial successor function having the same domain as lab, such that ∀v ∈ V : |succ(v)| = ar(lab(v))

Terms are interpreted as term graphs where lab and succ are undefined for variables This numbering is essential since we want to distinguish the term graphs corresponding to the terms f(a, b) and f(b, a)

# Term graph rewriting

How to apply a term rewrite rule  $\ell \rightarrow r$  on a term graph?

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > ... □

# Term graph rewriting

How to apply a term rewrite rule  $\ell \rightarrow r$  on a term graph?

Basic idea:

- Find a match of  $\ell$  in the graph
- Add r to the graph, connecting root and variables to those of the match of  $\ell$

イロト 不得 トイヨト イヨト 二日

How to apply a term rewrite rule  $\ell \rightarrow r$  on a term graph?

Basic idea:

- Find a match of  $\ell$  in the graph
- Add r to the graph, connecting root and variables to those of the match of  $\ell$

Precise definition is given by a *double push-out*:

where L, R are the term graphs of  $\ell, r, I$  is the *interface* (describing which parts of L are connected to which parts of R), and G is the graph that is rewritten to H

Two options:

Two options:

• Remove it: the *basic version*, or

ヘロン 人間 とくほと 人ほとう

Two options:

- Remove it: the basic version, or
- Keep it: the *extended version*

The extended version was studied before, and is a natural semantics if one is interested in the unfolded, possibly infinite term, and everything is considered modulo sharing/unsharing

伺 と く ヨ と く ヨ と

Two options:

- Remove it: the basic version, or
- Keep it: the *extended version*

The extended version was studied before, and is a natural semantics if one is interested in the unfolded, possibly infinite term, and everything is considered modulo sharing/unsharing

However, when considering term graphs as finite objects, and implicit sharing or unsharing is not allowed, then the basic version is the most natural one

・ 同 ト ・ 国 ト ・ 国 ト

Two options:

- Remove it: the basic version, or

For a related notion, namely *graph transformation systems* (GTS) in 2014 and 2015 we developed techniques for proving termination automatically, and implemented this in our tool *Grez* 

< ロ > < 同 > < 回 > < 回 > < □ > <

For a related notion, namely graph transformation systems (GTS) in 2014 and 2015 we developed techniques for proving termination automatically, and implemented this in our tool *Grez* 

GTS is extensively studied and used; standard semantics also based on double push-out

< ロ > < 同 > < 回 > < 回 > < □ > <

For a related notion, namely graph transformation systems (GTS) in 2014 and 2015 we developed techniques for proving termination automatically, and implemented this in our tool *Grez* 

GTS is extensively studied and used; standard semantics also based on double push-out

Main idea: transform TGRS to GTS in such a way that termination of resulting GTS implies termination of original TGRS

#### Difference between TGRS and GTS

Hans Zantema Termination of term graph rewriting

ヘロト ヘヨト ヘヨト ヘヨト

$$\label{eq:G} \begin{split} \mathsf{T}\mathsf{G} &= \mathsf{term} \ \mathsf{graph} \ \mathsf{in} \ \mathsf{T}\mathsf{G}\mathsf{R}\mathsf{S} \\ \mathsf{G} &= \mathsf{graph} \ \mathsf{in} \ \mathsf{G}\mathsf{T}\mathsf{S} \end{split}$$

・ロト ・回ト ・ヨト ・ヨト

 $\begin{array}{l} \mathsf{TG} = \mathsf{term} \ \mathsf{graph} \ \mathsf{in} \ \mathsf{TGRS} \\ \mathsf{G} = \mathsf{graph} \ \mathsf{in} \ \mathsf{GTS} \end{array}$ 

• Sometimes TG has a root: not desired for covering cycle rewriting

イロン 不同 とくほう イロン

-

 $\begin{array}{l} \mathsf{TG} = \mathsf{term} \ \mathsf{graph} \ \mathsf{in} \ \mathsf{TGRS} \\ \mathsf{G} = \mathsf{graph} \ \mathsf{in} \ \mathsf{GTS} \end{array}$ 

- Sometimes TG has a root: not desired for covering cycle rewriting
- In G the edges are labeled, in TG the nodes

・ 戸 ・ ・ ヨ ・ ・ ヨ ・

TG = term graph in TGRSG = graph in GTS

- Sometimes TG has a root: not desired for covering cycle rewriting
- In G the edges are labeled, in TG the nodes
- In G a node may have any number of outgoing edges, in TG there are exactly *n* numbered outgoing edges where *n* is the arity of the label of the node

・ 同 ト ・ ヨ ト ・ ヨ ト

TG = term graph in TGRSG = graph in GTS

- Sometimes TG has a root: not desired for covering cycle rewriting
- In G the edges are labeled, in TG the nodes
- In G a node may have any number of outgoing edges, in TG there are exactly *n* numbered outgoing edges where *n* is the arity of the label of the node

We have to transform TG to G, and give two ways to do so: the *function encoding* and the *number encoding* 

・ 同 ト ・ ヨ ト ・ ヨ ト

### Function encoding
